Find $\frac{dy}{dx}$ in, ⓘ eq^n of circle, $x^2+y^2=4$

ⓘⓘ eq^n of ellipse, $\frac{x^2}{9}+\frac{y^2}{16}=1$

ⓘⓘⓘ eq^n of Parabola, $y^2=16x$

ⓐ Eq^n of circle,

$x^2+y^2=4$

differentiating both sides w.r.to x

$\frac{d(x^2+y^2)}{dx} = \frac{d(4)}{dx}$

or, $\frac{d(x^2)}{dx} + \frac{dy^2}{dx} = 0$

or, $2x + \frac{dy^2}{dy} \times \frac{dy}{dx} = 0$

or, $2x + 2y \times \frac{dy}{dx} = 0$

or, $-2x = 2y\frac{dy}{dx}$

$\therefore \frac{dy}{dx} = -\frac{x}{y}$ #.

ⓑ eqⁿ of ellipse,

$$\frac{x^2}{9}+\frac{y^2}{16}=1$$

differentiating both sides ~~w~~ with respect to x.

$$\frac{d\left(\frac{x^2}{9}+\frac{y^2}{16}\right)}{dx}=\frac{d(1)}{dx}$$

or, $\frac{d(16x^2+9y^2)}{dx}=\frac{d(9\times16)}{dx}$

or, $16\frac{dx^2}{dx}+9\frac{dy^2}{dy}\times\frac{dy}{dx}=0$

or, $16\cdot2x+9\cdot2y\frac{dy}{dx}=0$

or, $18y\cdot\frac{dy}{dx}=-32x$

∴ $\frac{dy}{dx}=-\frac{16x}{9y}$ #.

ⓒ eqⁿ of Parabola,

$$y^2=16x$$

differentiating both sides w.r.t x.

w.r.t. y

$2y=\cancel{\frac{dx}{dy}}\times\frac{dy}{dx}$

$\frac{d(y^2)}{dx}=\frac{d(16x)}{dx}$

or, $\frac{dy^2}{dy}\times\frac{dy}{dx}=16\frac{dx}{dx}$

or, $\frac{dy}{dx}=\frac{16}{2y}$

∴ $\frac{dy}{dx}=\frac{8}{y}$ #

$$= \frac{10}{3} \text{ sq. unit.}$$

Hence the area enclosed by parabola $y = 2-x^2$ and line $y=-x$ is $A_1 + A_2$

$$A = \left(\frac{7}{6} + \frac{10}{3}\right) \text{sq. unit}$$

$y=\sqrt{x}$. Squaring

$y^2=x$ - - - (i)

$y=x-2$ - - - (ii)

Solving

$y=y^2-2$

or, $y^2-y-2=0$

or, $y^2-2y+y-2=0$

or $y(y-2)+1(y-2)=0$

$\therefore y=+2,-1$

$x=4, 1$

$\therefore x=4,1$

$y=2,-1$

when $x=1, y=1$

when $x=4, y=2$

$y=0$ $x=0$

$y=1$ $x=11$

$y=4$ $x=12$

Now,

$$\text{Area}(A)=\int_0^4 (\sqrt{x})\,dx-\int_2^4 (x-2)\,dx$$

$$=\frac{2}{3}\times 2^{\cancel{2}\cdot 3/\cancel{2}}-\left\{\left(\overset{8}{\frac{16}{2}}-\frac{4}{2}\right)-(2\times4-2\times2)\right\}$$

$$=\frac{16}{3}-(8-2-8+4)$$ -2

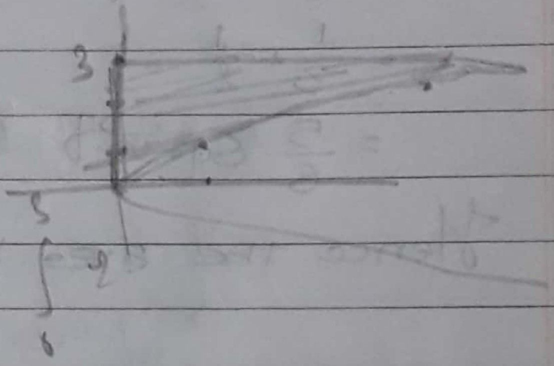
$x = 0$	$y = 0$
$x = 2$	$y = 1$
$x = 8$	$y = 2$
~~$x = 27$~~	$y = 3$

Now,

$$\text{Area (A)} = \int_0^3 2y^2 . dy$$



$$= 2 . \left[\frac{y^3}{3}\right]_0^3$$

$$= 2 . \left[\frac{3^3}{3} - \frac{0^3}{3}\right]$$

$x^2 + x - 2 = 0$

$x^2 + 2x - x - 2 = 0$

$y = u^2$

$x = 1$	$y = 1$
$x = 0$	$y = 0$
$x = 2$	$y = 4$
$x = 3$	$y = 9$

$\because u = +1, -2$

$y = 1, 4$

Now,

$$\text{Area (A)} = \int_0^1 u^2\,du + \int_1^2 (2-u)\,du$$

$$= \left[\frac{u^3}{3}\right]_0^1 + \left[2u\right]_1^2 - \left[\frac{u^2}{2}\right]_1^2$$

$$= \left(\frac{1}{3} - 0\right) + \left(2\times2 - 2\right) - \left(\frac{4}{2} - \frac{1}{2}\right)$$

$$= \frac{1}{3} + 2 - \frac{3}{2}$$

$$= \frac{1}{3} + \frac{1}{2}$$

$$= \frac{5}{6} \text{ Sq. unit}$$

Hence the area bounded is $5/6$ sq. unit

$y = u$

$\frac{1}{u^2} = u$

$\therefore u^3 = 1$

$\therefore x = 1$

$y = 1$

for curve,

$y = \frac{1}{u^2}$

when $u = 1$ $y = 1$

$u = 2$ $y = 0.25$

$$\text{Area (A)} = \int_0^1 u\,du + \int_1^2 u^{-2}\,du$$

$$= \cancel{\frac{1}{2}} + \left(\cancel{-\frac{1}{2}}\right) + 1 = 1 \text{ Sq. unit}$$

Hence the are in 1st quadrant bounded by line $y=x$, line $x=2$, curve $y=\frac{1}{x^2}$ is 1 sq. unit.

$x=2$ $y=8$

Now,

$$\text{Area (A)} = \int_0^1 x\,dx - \int_0^1 x^3\,dx$$

$$= \left[\frac{x^2}{2}\right]_0^1 - \left[\frac{x^4}{4}\right]_0^1$$

$$= \left(\frac{1}{2}-0\right) - \left(\frac{1}{4}-0\right)$$

$$= \frac{1}{2} - \frac{1}{4}$$

$$= \frac{2-1}{4}$$

$$= \frac{1}{4}$$

$$\cancel{= \int_0^1 \frac{3}{4}\,y^{1/3}\,dy - \int_0^1 y\,dy}$$

Either $x = 0$

$= x^3 - 64a^3$

or, $x^3 = 64a^3$

put Cube root on both side

$x = 4a$

Now,

$$\text{Area (A)} = \int_0^{4a} \sqrt{4ax}\,dx - \int_0^{4a} \frac{x^2}{4a}\,dx$$

$$= \int_0^{4a} 2\sqrt{a}\,x^{1/2}\,dx - \int_0^{4a} \frac{1}{4a}\,x^2\,dx$$

$$= 2\sqrt{a}\left[\frac{x^{3/2}}{3/2}\right]_0^{4a} - \frac{1}{4a}\left[\frac{x^3}{3}\right]_0^{4a}$$

$$= 2\sqrt{a}\times\frac{2}{3}\left[4a\right]^{3/2} - \frac{1}{4a\cancel{\times3}\times3}\left[\cancel{4}4a\right]^3$$

$$= \frac{4\sqrt{a}}{3}\,2^{2\cdot\frac{3}{2}}\,a^{3/2} - \frac{1}{3\cdot12a}\,64a^3$$

$$= \frac{4\sqrt{a}}{3}\times 8a^{3/2} - \frac{16a^2}{3}$$

$$= \frac{32a^{1/2+3/2}}{3} - \frac{16a^2}{3}$$

$$= \frac{32a^2 - 16a^2}{3}$$

$$= \frac{16a^2}{3}\text{ sq. unit}$$

$\therefore$ Req. Area is $\frac{16a^2}{3}$ sq. unit.

* Find the area bound by x-axis and parabola $y = 4 - u^2$.

$0 = 4 - u^2$

$\therefore u = \sqrt{4}$

$\therefore u = \pm 2$

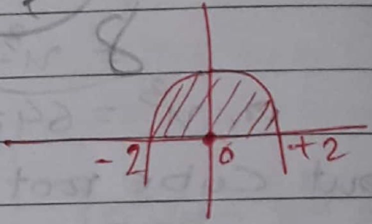
$y = 4$

$y = 4 - u^2$

when $u = 0$ $y = 4$

$u = 1$ $y = 3$

$u = 2$ $y = 0$



Now,

$$\text{Area (A)} = \int_0^2 (4 - u^2)\,du$$

$$= \int_0^2 4^{du} - \int_0^2 u^2\,dv$$

$$= [4u]_0^2 - \left[\frac{u^3}{3}\right]_0^2$$

$$= [4\times2 - 0] - \left[\frac{2^3}{3} - \frac{0}{3}\right]$$

$$= 8 - \frac{8}{3}$$

$$= \frac{24-8}{3}$$

$$= \frac{16}{3}$$

$\therefore$ Total area (A) $= \frac{16}{3} \times 2$

$$= \frac{3a^2}{2}\left[\frac{\pi}{6} - 0\right] + \left[\frac{\sin 6\frac{\pi}{6}}{6} - \frac{\sin 6.0^\circ}{6}\right]$$

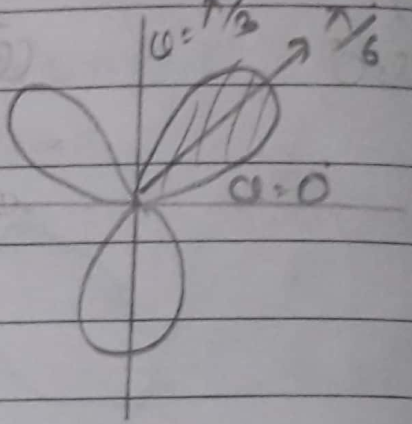
$$= \frac{\cancel{3}a^2}{2} \times \frac{\pi}{\cancel{6}2}$$

$$= \frac{\pi a^2}{4} \text{ sq. unit}$$

Hence the area of three leaved rose is $\frac{\pi a^2}{4}$ sq. unit

* Find the area of $r = a\sin 3\theta$

→ solution, $\theta = \pi/3$



$$\text{Area}(A) = \int_{\theta=0} \frac{1}{2} r^2 \, d\theta$$

$$= \frac{1}{2} \times 3 \int_{\theta=0}^{\theta=\pi/3} a^2 \sin^2 3\theta \, d\theta$$

$$= \frac{3a^2}{2} \int_{0}^{\pi/3} \left(\frac{1 - \cos 6\theta}{2} \right) d\theta$$

$$= \frac{3a^2}{2 \times 2} \int_{0}^{\pi/3} 1 \, d\theta - \int_{0}^{\pi/3} \cos 6\theta \, d\theta$$

$$= \frac{3a^2}{4} \left[\theta\right]_0^{\pi/3} - \left[\frac{\sin 6\theta}{6} \right]_0^{\pi/3}$$

$$= \frac{3a^2}{4} \times \left(\frac{\pi}{3} - 0 \right) - \left(\frac{\sin \overset{2}{\cancel{6}} \frac{\pi}{\cancel{3}}}{6} - \frac{\sin 6 \cdot 0}{6} \right)$$

$$= \frac{3a^2}{4} \left\{ \left(\frac{\pi}{3} \right) - \left(\frac{0}{6} - \frac{0}{6} \right) \right.$$

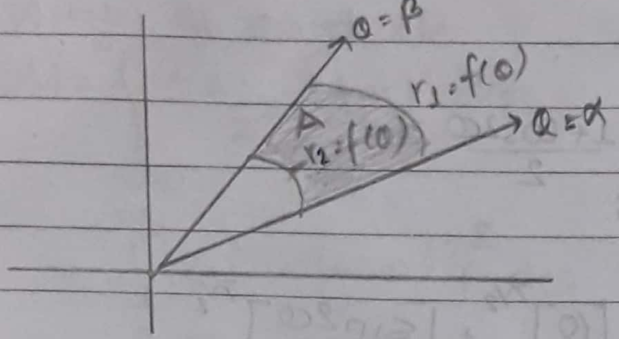
$$= \frac{3a^2}{4} \times \frac{\pi}{3}$$

$$= \frac{\cancel{3}\pi a^2}{\cancel{12}\,4}$$

$$= \frac{\pi a^2}{4} \text{ sq. unit}$$

Hence the area of a sin3θ is $\frac{\pi a^2}{4}$ sq. unit.

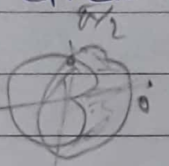
* Area between Polar Curves:

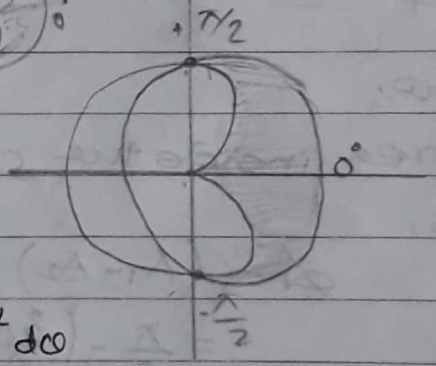


Area between Polar Curves $= \int_{\theta=\alpha}^{\theta=\beta} \frac{1}{2} r_1^2 \, d\theta - \int_{\theta=\alpha}^{\theta=\beta} \frac{1}{2} r_2^2 \, d\theta$

$$\boxed{\text{Area} = \frac{1}{2}\int_{\theta=\alpha}^{\theta=\beta} \frac{1}{2}(r_1^2 - r_2^2)\, d\theta}$$

* Find the area inside circle r=1 but outside the cardioide r= 1-cosθ





→ Solution,

$r_1 = 1$, $r_2 = 1 - \cos\theta$

$\therefore 1 = 1 - \cos\theta$

$\cos\theta = 0°$

$\therefore \theta = \pm\frac{\pi}{2}$

Area of circle $(A_1) = \int_{\theta=0}^{\theta=\pi/2} \frac{1}{2} r_1^2 \, d\theta$

$= \frac{1}{\cancel{2}} \times \cancel{2} \, [\theta]_0^{\pi/2}$

$= [\frac{\pi}{2} - 0]$

$= \frac{\pi}{2}$ sq. unit

Area of Cardioide $(A_2) = \int_{\theta=0}^{\theta=\pi/2} \frac{1}{2}(1-\cos\theta)^2 \, d\theta$

$= \int_{\theta=0}^{\pi/2} \frac{1}{\cancel{2}} \times \cancel{2} \, (1-\cos\theta)^2 \, d\theta$

$$= \int_{\theta=0^\circ}^{\theta=\pi/2} (1 - 2\cos\theta + \cos^2\theta)\, d\theta$$

$$= \int_{\theta=0^\circ}^{\theta=\pi/2} 1\, d\theta - 2\int_{\theta=0^\circ}^{\theta=\pi/2} \cos\theta + \int_{\theta=0^\circ}^{\theta=\pi/2} \frac{1+\cos 2\theta}{2}\, d\theta$$

$$= [\theta]_0^{\pi/2} - 2[\sin\theta]_0^{\pi/2} + \frac{1}{2}[\theta]_0^{\pi/2} + \left[\frac{\sin 2\theta}{2}\right]_0^{\pi/2}$$

$$= \left(\frac{\pi}{2}-0\right) - 2\left[\sin\frac{\pi}{2} - \sin 0^\circ\right) + \frac{1}{2}\left(\frac{\pi}{2}-0\right) + \left(\frac{\sin 2.\frac{\pi}{2}}{2} - \frac{\sin 2.0^\circ}{2}\right)$$

$$= \frac{\pi}{2} - 2\times 1 + \frac{1}{2}\times\frac{\pi}{2} + \frac{1}{2}\left(\frac{0}{2} - \frac{0}{2}\right)$$

$$= \frac{\pi}{2} - 2 + \frac{\pi}{4}$$

$$= \frac{3\pi}{4} - 2$$

Now,

Area inside the circle but outside the cardioide is,

$$A = (A_1 - A_2)$$

$$= \frac{\pi}{2} - \left(\frac{3\pi}{4} - 2\right)$$

$$= \frac{\pi}{2} - \frac{3\pi}{4} + 2 \quad = \frac{2\pi - 3\pi + 2}{4}$$

$$=$$

$$= 2 - \frac{\pi}{4} \text{ sq. unit}$$

* Find the area shared by the circle $r=2$ and cardioide $r = 2(1-\cos\theta)$

→ solution,

$r = 2$, $r = 2(1-\cos\theta)$

$2 = 2(1-\cos\theta)$

or, $1 - \cos\theta - 1$

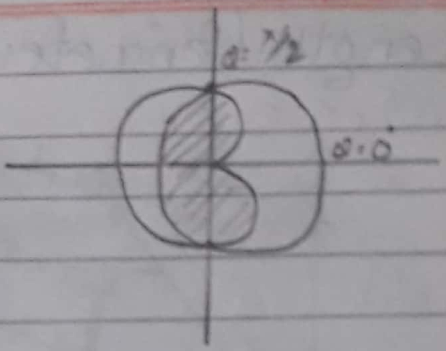
$\cos\theta = 1 - 1$

$\therefore \theta = \pm \pi/2$

here,

Area of cardiode

$(A_1) = \int_{\theta=0}^{\theta=\pi/2} \frac{1}{2}\times 2 (r)^2 d\theta$



$= \int_0^{\pi/2} \{2(1-\cos\theta)\}^2 d\theta$

$= 4\int_0^{\pi/2} (1-2\cos\theta+\cos^2\theta) d\theta$

$= 4\{[\theta]_0^{\pi/2} - 2[\sin\theta]_0^{\pi/2} + \frac{1}{2}\{[\theta]_0^{\pi/2} + [\frac{\sin 2\theta}{2}]_0^{\pi/2}\}$

$= 4\{[\frac{\pi}{2}-0] - 2[\sin\frac{\pi}{2} - \sin 0] + \frac{1}{2}\{[\frac{\pi}{2}-0] + \frac{\sin 2\frac{\pi}{2}}{2} - \frac{\sin 0}{2}$

$= 4\frac{\pi}{2} - 4\times2(1-0) + \frac{4}{2}\frac{\pi}{2} + 4[\frac{0}{2}-\frac{0}{2}]$

$= 2\pi - 8 + \pi + 0$

$= 3\pi - 8$

Again,

Area of Circle $(A_2) = \int_{\theta=0}^{\theta=\pi/2} \frac{1}{2}\times 2 (2)^2 d\theta$

$= 4\int_0^{\pi/2} 1\, d\theta$

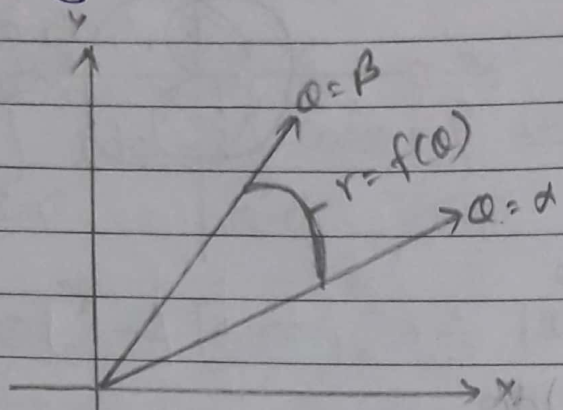
$= 4[\theta]_0^{\pi/2} = 4[\frac{\pi}{2}-0] = \frac{4\pi}{2} = 2\pi$

Hence Area covered by circle & Cardioide is

$A = A_1 + A_2 = 3\pi - 8 + 2\pi$

$= (5\pi - 8)$ sq. units

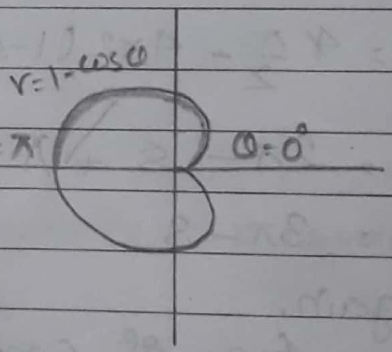
* Length (Perimeter of the Polar Curve):



$$\boxed{L=\int_{\theta=\alpha}^{\theta=\beta}\sqrt{r^2+\left(\frac{dr}{d\theta}\right)^2}\,d\theta}$$

* Find the length of Cardiode $r = 1 - \cos\theta$

→ Solution,



$r = 1 - \cos\theta$

$r^2 = 1 - 2\cos\theta + \cos^2\theta$

$$\left(\frac{dr}{d\theta}\right)^2 = \frac{d(1-\cos\theta)}{d\theta}$$

$$= \frac{d1}{d\theta} - \frac{d\cos\theta}{d\theta}$$

$$= 0 - x - \sin\theta$$

$$\therefore \left(\frac{dr}{d\theta}\right)^2 = (\sin\theta)^2$$

$$\therefore \text{length } (L) = \int_{\theta=0^\circ}^{\theta=\pi} \sqrt{1-2\cos\theta+\cos^2\theta+\sin^2\theta}\, d\theta$$

$$= \int_{\theta=0}^{\theta=\pi} \sqrt{1 - 2\cos\theta + 1}\quad d\varphi$$

$\therefore \sin^2\theta = \frac{1-\cos 2\theta}{2}$

$$= \int_0^{\pi} \sqrt{2(1-\cos\theta)}\, d\varphi$$

$2\sin^2\theta/_2 = 1 - \cos 2\theta/_2$

$$= \int_0^{\pi} \sqrt{2.2\sin^2\theta/_2}\ d\theta$$

$\therefore 2\sin^2\theta/_2 = 1 - \cos\theta$

$= \int_0^{\pi} 2 \sin \theta/2 \; d\theta$

$= 2 \left[\frac{-\cos \frac{\theta}{2}}{1/2} \right]_0^{\pi} = 2.2\left[-\cos \pi/2 + \cos 0/2 \right]$

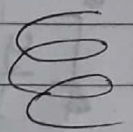
$= 4 \left[-0 + 1 \right]$

$= 4 \times 1 = 4 \times 2$ unit $= 8$ unit

Hence the perimeter of Cordioide is 8 unit.

* Find the length of spira' $r = \theta^2$, $0 \le \theta \le \sqrt{5}$

→ Solution,



$r = \theta^2$

$r^2 = \theta^4$

$\frac{dr}{d\theta} = \frac{d\theta^2}{d\theta} = 2\theta$

$\left(\frac{dr}{d\theta}\right)^2 = (2\theta)^2 = 4\theta^2$

$r^2 + \left(\frac{dr}{d\theta}\right)^2 = \theta^4 + 4\theta^2$

$= \theta^2(\theta^2 + 4)$

Now,

length $(L) = \int_{\theta_2}^{\theta_2} \sqrt{r^2 + \left(\frac{dr}{d\theta}\right)^2} \; d\theta$

$= \int_0^{\sqrt{5}} \sqrt{\theta^2(\theta^2+4)} \; d\theta$

$= \int_0^{\sqrt{5}} \sqrt{\theta^2+4} \; \theta d\theta$

let $y = \theta^2 + 4$

diff. $y = \theta^2 + 4$ w.r.to $d\theta$

$\frac{dy}{d\theta} = 2\theta$ $\therefore dy = 2\theta \, d\theta$ $\therefore \frac{dy}{2} = \theta \, d\theta$

$y = \theta^2 + 4$

when $\theta = 0$, when $\theta = \sqrt{5}$

$y = 4$ $y = (\sqrt{5})^2 + 4$

$= 9$

Now,

$$L = \int_4^9 \sqrt{y} \cdot \frac{dy}{2}$$

$$= \frac{1}{2} \int_4^9 y^{1/2} dy$$

$$= \frac{1}{2} \left[\frac{y^{1/2+1}}{\frac{1}{2}+1} \right]_4^9$$

$$= \frac{1}{2} \left[\frac{y^{3/2}}{3/2} \right]_4^9$$

$$= \frac{1}{2} \times \frac{2}{3} \left[9^{3/2} - 4^{3/2} \right]$$

$$= \frac{1}{3} \left[3^{2 \cdot 3/2} - 2^{2 \cdot 3/2} \right]$$

$$= \frac{1}{3} [27 - 8)$$

$$= \frac{19}{3}$$

$= 6.33$ unit

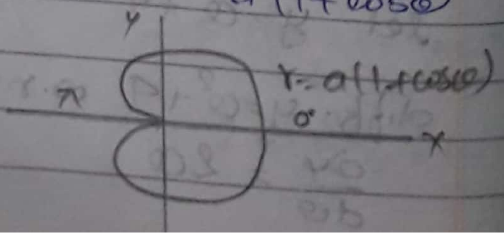
Hence the length of Spiral is 6.33 unit.

* Find the length of cardioide $r = a(1+\cos\theta)$

→ For Cardiode

$\theta_1 = 0$

$\theta_2 = \pi$



→ $r^2 = a(1+\cos\theta)$

$r^2 = a^2(1+2\cos\theta+\cos^2\theta)$

$\frac{dr}{d\theta} = \frac{a\,d(1+\cos\theta)}{dr} = -a\sin\theta$

$\therefore \left(\frac{dr}{d\theta}\right)^2 = a^2\sin^2\theta$

Now,

Length(L) $= \int_{\theta=0}^{\theta=\pi}\sqrt{r^2+\left(\frac{dr}{d\theta}\right)^2}\,d\theta$

$= \int_{\theta=0}^{\theta=\pi}\sqrt{a^2(1+2\cos\theta+\cos^2\theta)+a^2\sin^2\theta}\,d\theta$

$= \int_{\theta=0}^{\theta=\pi} a\sqrt{1+2\cos\theta+\cos^2\theta+\sin^2\theta}\,d\theta$

$= a\int_{\theta=0}^{\theta=\pi}\sqrt{2(1+\cos\theta)}$

$\cos^2\theta = \frac{1+\cos2\theta}{2}$

$2\cos^2\theta/2 = 1+\cos2\theta/2$

$\therefore 2\cos^2\theta/2 = 1+\cos\theta$

$= a\int_{\theta=0}^{\pi}\sqrt{2.2\cos^2\theta/2} = 2\cos\theta/2$

$= 2a\left[\frac{+\sin\frac{\theta}{2}}{1/2}\right]_0^\pi$

$= 2a\times\frac{2}{1}\left[+\sin\frac{\pi}{2} - \sin\frac{0}{2}\right]$

$= 4a(1-0)$

$= 4a$

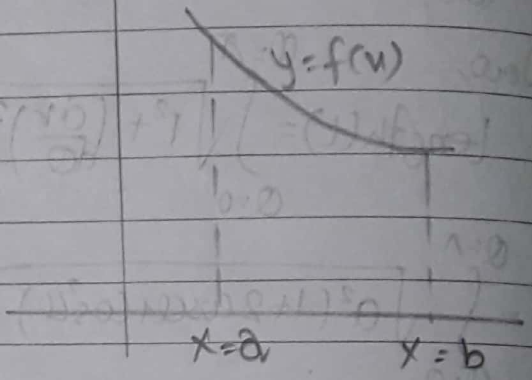
$\therefore$ total length of cardioide $= 4a\times2$

$= 8a$ units.

* Length for a function $y=f(x)$, $a \le x \le b$.

If a function is continuous and differentiable on closed interval [a,b], then,

$$L=\int_{x=a}^{x=b}\sqrt{1+\left(\frac{dy}{dx}\right)^2}\,dx$$



For function, $x=f(y)$

$c \le y \le d$

$$L=\int_{x=c}^{x=d}\sqrt{1+\left(\frac{dx}{dy}\right)^2}\,dy$$

Note:

If f(x) is not differentiable on closed interval [a,b] then use f(y) and vice-versa.

* Find the length of curve $y=x^{3/2}$, $0 \le x \le 1$.

→ Solution,

$$\frac{dy}{dx}=\frac{d\,x^{3/2}}{dx}=\frac{3}{2}x^{3/2-1}=\frac{3}{2}x^{1/2}$$

∵ It is differentiable at $x \in [0,1]$

Now,

$$1+\left(\frac{dy}{dx}\right)^2=1+\left(\frac{3}{2}x^{1/2}\right)=1+\frac{9}{4}x=\frac{4+9x}{4}$$

Now,

$$\text{length}(L)=\int_{x=0}^{x=1}\sqrt{1+\left(\frac{dy}{dx}\right)^2}\,dx$$

$$=\int_0^1\sqrt{\frac{4+9x}{4}}\,dx$$

$$=\frac{1}{2}\int_0^1\sqrt{4+9x}\,dx$$

$$= \frac{1}{2}\int_0^1 (4+9x)^{1/2}\,dx$$

$$= \frac{1}{2}\left[\frac{(4+9x)^{1/2+1}}{\frac{3}{2}\times 9}\right]_0^1$$

$$= \frac{1}{\cancel{2}}\times\frac{\cancel{2}}{3\times 9}\left[(4+9x)^{3/2}\right]_0^1$$

$$= \frac{1}{27}\,(4+9.1)^{3/2} - (4+9.0)^{3/2}$$

$$= \frac{1}{27}\,(13)^{3/2} - (4)^{3/2}$$

$$= \frac{1}{27}\times 46.87 - 2^{2^{3/2}}$$

$$= \frac{38.87}{27}$$

$= 1.439$ unit

$\therefore$ length of curve is 1.439 unit.

* Find the length of curve $y = \left(\frac{x}{2}\right)^{2/3}$ from $x=0$ to $x=2$

→ Solution,

$$\cancel{\frac{dy}{dx} = \left(\frac{1}{2}\right)^{2/3}\times\frac{2}{3}(x)^{2/3-1} = \frac{1}{3\sqrt[3]{x}}}$$

$$\frac{dy}{dx} = \left(\frac{1}{2}\right)^{2/3}\times\frac{2}{3}(x)^{2/3-1} = 0.62\times\frac{2}{3\sqrt{x}} = \frac{0.41}{\sqrt{x}}$$

when $x=0$ $= \frac{0.41}{0} = \infty$

so it is not differentiable at $x\in[0,2]$

Again,

$\frac{dx}{dy}$? so, $y = \left(\frac{x}{2}\right)^{2/3}$

$$y^{3/2} = \frac{x}{2} \qquad \therefore x = 2y^{3/2}$$

$x = 2y^{3/2}$

when $x = 0$ when $x = 2$

$0 = 2y^{3/2}$ $2 = \cancel{2}y^{3/2}$

$\therefore y = 0$ $y = 1$

Now,

$$\frac{dx}{dy} = 2\frac{dy^{3/2}}{dy} = \cancel{2}\times\frac{3}{\cancel{2}}y^{3/2-1}$$

$$= 3y^{1/2}$$

$$\therefore 1 + \left(\frac{dy}{dy}\right)^2 = 1 + (3y^{1/2})^2 = 1 + 9y$$

$$\therefore \text{length} (L) = \int_{y=0}^{y=1} \sqrt{1+\left(\frac{dx}{dy}\right)^2}\, dy$$

$$= \int_0^1 \sqrt{1+9y}\, dy$$

$$= \int_0^1 (1+9y)^{1/2}\, dy$$

$$= \int_0^4 \left[\frac{(1+9y)^{1/2+1}}{(1/2+1).9}\right]_0^1$$

$$= \frac{2}{3.9}(1+9.1)^{3/2} - (1+9.0)^{3/2}$$

$$= \frac{2}{3.9}(10)^{3/2} - 1$$

$$= \frac{61.24}{3\times 9}$$

$$= \frac{61.24}{27}$$

$= 2.26$ unit

Hence the length curve is 2.26 unit.

* Find the length of curve $y = \frac{4\sqrt{2}}{3} x^{3/2} - 1 \quad 0 \le x \le 1$.

→ Solution,

$$\frac{dy}{dx} = \frac{d \frac{4\sqrt{2}}{3} x^{3/2} - 1}{dx}$$

$$= \frac{4\sqrt{2}}{\cancel{3}} \times \frac{3}{\cancel{2}} x^{3/2 - 1} - 0$$

$$= 2\sqrt{2} x^{1/2}$$

$$= 2\sqrt{2x}$$

Now,

$$1 + \left(\frac{dy}{dx}\right)^2 = (2\sqrt{2x})^2 = 1 + 8x$$

Now,

$$\text{length } (l) = \int_0^1 \sqrt{1 + \left(\frac{dy}{dx}\right)^2} \, dx$$

$$= \int_0^1 \sqrt{1 + 8x} \quad dx$$

$$= \int_0^1 (1 + 8x)^{1/2} dx$$

$$= \left[\frac{(1 + 8x)^{1/2+1}}{(1/2 + 1) \cdot 8}\right]_0^1$$

$$= (1 + 8x)^{3/2} \times \frac{2}{3 \times 8}$$

$$= \frac{2}{3} (1 + 8 \cdot 1)^{3/2} - (1 + 8 \times 0)^{3/2}$$

$$= \frac{2}{3 \times 8} (3)^{2 \cdot 3/2} - 1^{3/2}$$

$$= \frac{2 \times 26}{24}$$

$= 2.16$ unit

Hence the length of curve is 2.16 unit

* Find the length of curve $y = \frac{1}{3}(x^2+2)^{3/2}$ $0 \le x \le 3$.

→ Solution,

$$\frac{dy}{dx} = \frac{1}{\cancel{3}} \times \frac{\cancel{3}}{2} (x^2+2)^{3/2-1} = \frac{1}{2} (x^2+2)^{1/2}$$

Now,

$$1 + \left(\frac{dy}{dx}\right)^2 = 1 + \left(\frac{1}{2}(x^2+2)^{1/2}\right)^2$$

$$= 1 + \frac{1}{4}(x^2+2)$$

$$= \frac{4+(x^2+2)}{4}$$

$$= \frac{6+x^2}{4}$$

$$\frac{dy}{dx} = \frac{1}{3} \frac{d(x^2+2)^{3/2}}{d(x^2+2)} \times \frac{d(x^2+2)}{dx}$$

$$= \frac{1}{\cancel{3}} \times \frac{\cancel{3}}{\cancel{2}} (x^2+2)^{3/2-1} \times 2x$$

$$= (x^2+2)^{1/2} \cdot 2x$$

$$1 + \left(\frac{dy}{dx}\right)^2 = 1 + 4x^2(x^2+2)$$

→ Solution,

$$y = \frac{1}{3}(x^2+2)^{3/2}$$

Now,

$$\frac{dy}{dx} = \frac{1}{3} \frac{d(x^2+2)^{3/2}}{d(x^2+2)} \times \frac{d(x^2+2)}{dx}$$

$$= \frac{1}{\cancel{3}} \times \frac{\cancel{3}}{\cancel{2}} (x^2+2)^{1/2} \times \cancel{2}x$$

$$= x(x^2+2)^{1/2}$$

$$1 + \left(\frac{dy}{dx}\right)^2 = 1 + \left\{x(x^2+2)^{1/2}\right\}^2 = 1 + x^2(x^2+2)$$

$$= 1 + x^4 + 2x^2$$

$= 1+2x^2+x^4$

$= (1+x^2)^2$

Now,

$$\text{length}(l) = \int_0^3 \sqrt{(1+x^2)^2}\, dx$$

$$= \int_0^3 (1+x^2)\, dx$$

$$= [x]_0^3 + \left[\frac{x^3}{3}\right]_0^3$$

$$= (3-0) + \left(\frac{3^3}{3} - \frac{0}{3}\right)$$

$$= 3 + \frac{\cancel{27}\,9}{3}$$

$= 12$ unit.

Hence the length of curve is 12 unit.

* Find the length of curve $x = \left(\frac{y^4}{4}\right) + \frac{1}{8y^2}$ $\quad 1 \le y \le 2$

→ solution,

$$\frac{dx}{dy} = \frac{d\left(\frac{y^4}{4}\right) + \frac{1}{8y^2}}{dy}$$

$$= \frac{1}{4} \times 4y^3 + \frac{1}{8} \times (-2)\, y^{-3}$$

$$= y^3 - \frac{1}{4y^3}$$

Now,

$$1 + \left(\frac{dx}{dy}\right)^2 = 1 + \left(y^3 - \frac{1}{4y^3}\right)^2$$

$$= \left\{1 + y^3 - \cancel{2}.\, y^3 . \frac{1}{\underset{2}{\cancel{4}}y^3} + \left(\frac{1}{4y^3}\right)^2\right\}$$

$$= 1 - \frac{1}{2} + y^3 + \left(\frac{1}{4y^3}\right)^2$$

$$= (y)^3 + 2.\, y^3 . \frac{1}{4y^3} + \left(\frac{1}{4y^3}\right)^2$$

$$= \left(y^3+\frac{1}{4y^3}\right)^2$$

Now,

$$\text{Length} = \int^{2} \sqrt{1+\left(\frac{dx}{dy}\right)^2}\,dy$$

$$= \int_{1}^{2} \sqrt{\left(y^3+\frac{1}{4y^3}\right)^2}\,dy$$

$$= \int_{1}^{2} \left(y^3+\frac{1}{4y^3}\right)dy$$

$$= \left[\frac{y^4}{4}\right]_1^2 + \frac{1}{4}\left[\frac{y^{-3+1}}{-3+1}\right]_1^2$$

$$= \left(\frac{2^4-1}{4}\right) + \frac{1}{4}\left[\frac{2^{-2}-1^{-2}}{-2}\right]$$

$$= \left(\frac{16-1}{4}\right) + \frac{1}{-8}\left[\frac{1}{2^2}-\frac{1}{1^2}\right]$$

$$= \frac{15}{4} - \frac{1}{8}\left(\frac{1}{4}-1\right)$$

$= 3.75 - 0.125\ (-0.75)$

$= 3.75 + 0.093$

$= 3.84375$ unit

Hence the length of curve is 3.84 unit.

$$= y^2 - \frac{1}{4y^2}$$

Now,

$$1+\left(\frac{dx}{dy}\right)^2 = 1+\left(y^2-\frac{1}{4y^2}\right)^2$$

$$= 1-\frac{1}{2}+(y^2)^2+\left(\frac{1}{4y^2}\right)^2$$

$$= \frac{1}{2}+(y^2)^2+\left(\frac{1}{4y^2}\right)^2$$

$$=(y^2)^2+2\cdot y^2)\frac{1}{4y^2}+\left(\frac{1}{4y^2}\right)^2$$

$$=\frac{26}{3}+\frac{2}{-4}\left[\frac{1}{3}-\frac{1}{1}\right)$$

$$= 8.66-0.25\times(-0.666)$$

$$= 8.60+0.1666$$

$$= 8.766 \text{ unit}$$

$\therefore$ The length of curve is 8.766 unit.

* Find the length of the circle $x^2+y^2=a^2$

$$x^2+y^2=a^2$$

differentiating both sides w.r. to x

we get

$0 = a\sin\theta$

$\therefore \theta = \sin^{-1}(0^\circ) = 0^\circ$

when $x = a$

$a = a\sin\theta$

$\therefore \sin\theta = 1$

$$= \frac{3a^{1/3}}{2}\cdot a^{2/3}$$

$$= \frac{3}{2}\times a^{1/3+2/3}$$

$$= \frac{3a}{2}$$

Total: Area of the asteroid is $= \overset{2}{4} \times \frac{3a}{2}$ $= 6a$ unit.

Length of Parametric Curve:

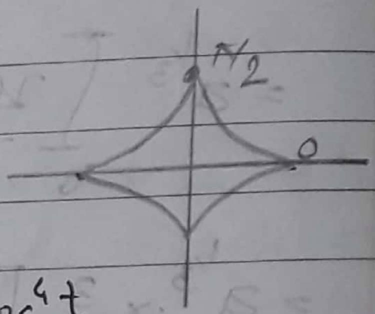
If $x = f(t)$ and $y = g(t)$ and $a \le t \le b$

then,

$$L = \int_{t=a}^{t=b} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt$$

* Find the length of asteroid $x = \cos^3 t$ and $y = \sin^3 t$
$0 \le t \le \pi/2$

→ Solution,



$$\frac{dx}{dt} = \frac{d\cos^3 t}{d\cos t} \times \frac{d\cos t}{dt}$$

$$= 3\cos^2 t \times (-\sin t)$$

$$\therefore \left(\frac{dx}{dt}\right)^2 = -3\sin t \cdot \cos^2 t = 9\sin^2 t \cdot \cos^4 t$$

$$\frac{dy}{dt} = \frac{d\sin^3 t}{d\sin t} \times \frac{d\sin t}{dt}$$

$$= 3\sin^2 t \times \cos t$$

$$\therefore \left(\frac{dy}{dt}\right)^2 = 3\sin^2 t \cdot \cos t = 9\sin^4 t \cdot \cos^2 t$$

Now,

$$L = \int_{t=0}^{t=\pi/2} \sqrt{9\sin^2 t \cdot \cos^4 t + 9\sin^4 t \cdot \cos^2 t}\, dt$$

~~$$= \int_{t=0}^{t=\pi/2} \sqrt{9\sin^2 t\cos^2 t\,(\cos^2 t + \sin^2 t)}\, dt$$~~

~~$$= 3 \int_{t=0}^{t=\pi/2} \sin t \cdot \cos t\, dt$$~~

~~$$= \frac{3}{2} \int_{t=0}^{t=2\pi} 2 \cdot \sin t \cdot \cos t\, dt$$~~

~~$$= \frac{3}{2} \int_{t=0}^{t=2\pi} \sin 2t\, dt$$~~

~~$$= \frac{3}{2}\left[\frac{-\cos 2t}{2}\right]_0^{2\pi}$$~~

~~$$= \frac{3}{2}\left[-\frac{\cos 2.2\pi}{2} + \frac{\cos 2.0}{2}\right]$$~~

~~$$= \frac{3}{4}\,(\,)\,(-$$~~

~~$$= \frac{3}{4}$$~~

∴ Total length of asteroid = 4×

Now,

$$L = \int_{t=0}^{t=\pi/2} \sqrt{9\sin^2 t \cdot \cos^2 t\,(\cos^2 t + \sin^2 t)}\,dt$$

$$= 3\int_0^{\pi/2} \sin t \cdot \cos t \cdot dt$$

$$= \frac{3}{2}\int_0^{\pi/2} 2 \cdot \sin t \cdot \cos t\ dt$$

$$= \frac{3}{2}\int_0^{\pi/2} \sin 2t\ dt$$

$$= \frac{3}{2}\left[-\frac{\cos 2t}{2}\right]_0^{\pi/2}$$

$$= \frac{3}{2}\left[-\frac{\cos 2 \cdot \pi/2}{2} + \frac{\cos 2 \cdot 0}{2}\right]$$

$$= \frac{3}{4}\left[+1+1\right)$$

$$= \frac{3}{4} \times 2$$

$$= \frac{3}{2}$$

∴ Total length of asteroid $= 2\cancel{4} \times \frac{3}{\cancel{2}}$

$= 6$ unit.

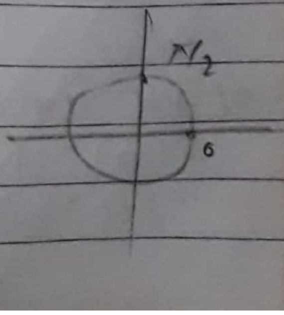
here,

we have,



$x = a\cos t$ $\quad$ $y = a\sin t$

$\therefore \frac{dx}{dt} = -a\sin t$ $\quad$ $\frac{dy}{dt} = a\cos t$

Now,

$$\text{length} = \int_0^{2\pi} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt$$

$$= \int_0^{2\pi} \sqrt{a^2\sin^2 t + a^2\cos^2 t}\, dt$$

$$= \int_0^{2\pi} \sqrt{a^2(\sin^2 t + \cos^2 t)}\, dt$$

$$= \int_0^{2\pi} a\, dt$$

$$= a\,[t]_0^{2\pi}$$

$$= a \times [2\pi - 0]$$

$= 2\pi a$ unit.

Hence length of circle is $2\pi a$ unit.

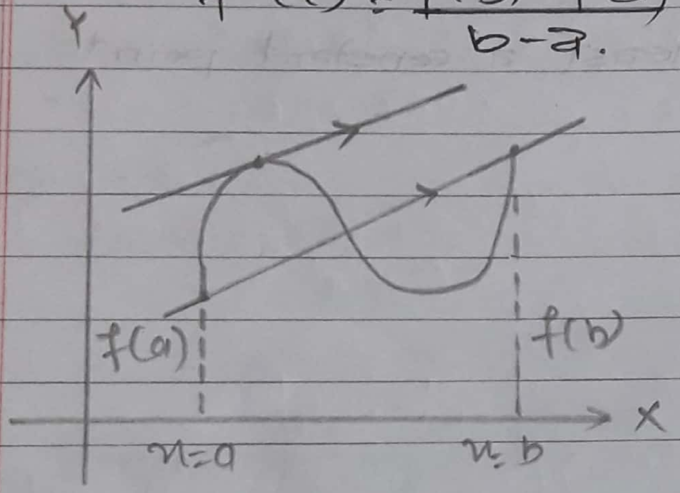
Lagrange Mean Value Theorem (MVT)

If a function f(x) is
a) continuous in closed interval [a,b]
b) differentiable in open interval (a,b)
then,
there exists at least a point $c \in (a,b)$
such that
$$f'(c) = \frac{f(b)-f(a)}{b-a}.$$



* verify Mean Value Theorum for the following functions.

a) $f(x) = x(x-1)(x-2) \quad x \in [0, +\frac{1}{2}]$

→ solution,

$f(x) = x^2 - x(x-2)$
$= x^2(x-2) - x(x-2)$
$= x^3 - 2x^2 - x^2 + 2x$
$= x^3 - 3x^2 + 2x$

Since the function f(x) is polynomial function which exists for all $x \in [0, \frac{1}{2}]$

$f'(x) = 3x^2 - 6x + 2$

function f(x) is differentiable for all $x \in (0, \frac{1}{2})$

then

there exists at least a point $c \in (0, \frac{1}{2})$

such that
$$f'(c) = \frac{f(b)-f(a)}{b-a}$$

$f(a) = f(0) = 0^3 - 30^2 + 2\times 0 = 0$

$f(b) = f(\frac{1}{2}) = (\frac{1}{2})^3 - 3(\frac{1}{2})^2 + \frac{1}{2}\times 2$

$= \frac{1}{8} - \frac{3}{4} + 1$

$= \frac{1}{8} - \frac{3}{4} + 1 = \frac{1-6+8}{8} = \frac{3}{8}$

Now,

$f'(c) = \frac{f(b) \cdot f(a)}{b-a}$

$3c^2 - 6c + 2 = \frac{\frac{3}{8} - 0}{\frac{1}{2} - 0}$

$3c^2 - 6c + 2 = \frac{3}{\cancel{8}_4} \times \frac{\cancel{2}}{1}$

$12c^2 - 24c + 8 = 3$

$12c^2 - 24c + 5 = 0$ - - - -(i)

Comparing eq^n (i) with $ax^2 + bx + c$

where $a = 12$ $b = -24$ $c = 5$

Now,

$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$

$= \frac{+24 \pm \sqrt{(-24)^2 - 4\times 12\times 5}}{2\times 12}$

$= \frac{24 \pm 18.33}{24}$

$= \frac{42.33}{24}, \frac{5.67}{24}$

$= 1.76, 0.236$

$\because c = 1.76 \notin (0, \frac{1}{2})$

$\therefore c = 0.236 \in (0, \frac{1}{2})$

Hence Mean Value Theorum is verified.

$$= \frac{1}{\cancel{2}\sqrt{x^2-4}} \times \cancel{2}x$$

$$= \frac{x}{\sqrt{x^2-4}}$$

function f(x) is differentiable at open interval for all $x \in (2,4)$

then,

there exists at least a point $c \in (2,4)$ such that,

$$f'(c) = \frac{f(b)-f(a)}{b-a}$$

$$f(a) = f(2) = \sqrt{2^2-4} = 0$$

Now,

$$f'(c) = \frac{f(b)-f(a)}{b-a}$$

$$\frac{c^2}{c^2-4} = \frac{\cancel{2}\cancel{2}\cancel{\sqrt{}}3}{\cancel{2}}$$

$$c^2 = 3c^2 - 12$$

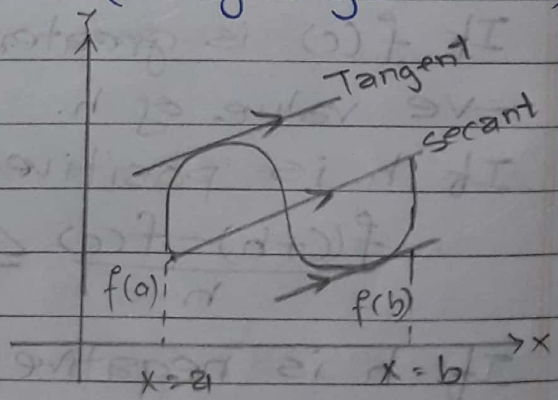
Geometrical Interpretation : (Langrange MVT)

→ In the continuous curve of function f(x), tangent can be drawn from each point of the curve.



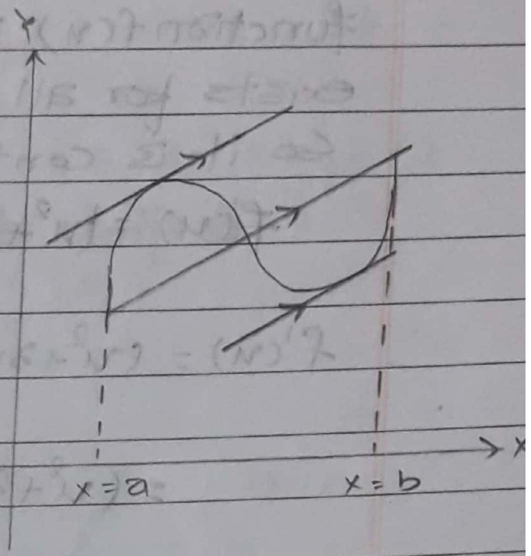
There exists at least a point where tangent can be drawn which is parallel to the secand joining the ends points of the function.

Proof (Lagrange Mean Value Theorem)

Defining a new function $\phi(x)$ as

$$\phi(x) = f(x) + Ax \text{ --- (i)}$$

where A is a constant to be determined such that,



$$\phi(a) = \phi(b)$$

or, $f(a) + Aa = f(b) + Ab$

or, $A(a-b) = f(b) - f(a)$

or, $A = -\dfrac{f(b)-f(a)}{b-a}$

Putting the value of A in eq^n (1),

$$\phi(x) = f(x) - \frac{f(b)-f(a)}{b-a}x$$

and

$$\phi'(x) = f'(x) - \frac{f(b)-f(a)}{b-a}$$

Since the function $\phi(x)$ is continuous in $x \in [a,b]$, differentiable in $x \in (a,b)$ and $\phi(a) = \phi(b)$. Then by Rolle's Theorum there exists at least a point $c \in (a,b)$, such that,

$$\phi'(c) = 0$$

or, $f'(c) - \dfrac{f(b)-f(a)}{b-a} = 0$

or $f'(c) = \dfrac{f(b)-f(a)}{b-a}$

Hence proved

$f(x) = x(x+3)e^{-x/2}, \quad x \in [-3,0]$

→ Solution,

So it is continuous

$$f(x) = (x^2+3x)e^{-x/2}$$

$$f'(x) = (x^2+3x)\frac{de^{-x/2}}{dx} + e^{-x/2}\frac{d(x^2+3x)}{dx}$$

$$= (x^2+3x)\left(-\tfrac{1}{2}\right)e^{-x/2} + e^{-x/2}(2x+3)$$

$$= e^{x/2}\left(\frac{(x^2+3x)(-1)}{2} \overset{+}{\bullet} (2x+3)\right)$$

$$= e^{-x/2}\left(\frac{x^2+3x-4x-6}{2}\right)$$

$$= \frac{e^{-x/2}}{2}(x^2-x-6)$$

which is differentiable for all $x \in (-3,0)$

then,

$f(a) = f(-3) = (-3)^2 + 3(-3)\, e^{+3/2}$

$= 9 - 9\, e^{-3/2}$

$= 0$.

$f(b) = f(0) = 0$

$f(a) = f(b) = 0$

then there exists at least a point $c \in (-3,0)$

Such that

$f'(c) = 0$

$\frac{e^{-c/2}}{2}(c^2-c-6) = 0$

$c^2-c-6=0$

or, $c^2 - 3c + 2c - 6 = 0$

or $c(c-3) + 2(c-3)$

or $(c-3)(c+2) = 0$

Either,

$c = +3 \notin (-3, 0)$

$c = -2 \in (-3, 0)$

so, $y = +a$ ∴ $a = 2$

$x^2 = -4ay$

$x^2 = -4 \times 2y$

$\boxed{x^2 + 8y = 0}$ is req eqⁿ of parabola

c) vertex (-2,0), eqⁿ of directrix (x) = 2

→ Solution,

Vertex $(h,k) = (-2,0)$ here $x=2$ in direct. so eqⁿ of P is $(y-k)^2$

eqⁿ of directrix (x) = 2

we have,

$(y-k)^2 = 4a(x-h)$

or, $(y-0)^2 = -4 \times a(x+2)$

For a

we have,

eqⁿ of directrix (x) = [illegible] h - a

$2 = -2 - a$

$a = -4$

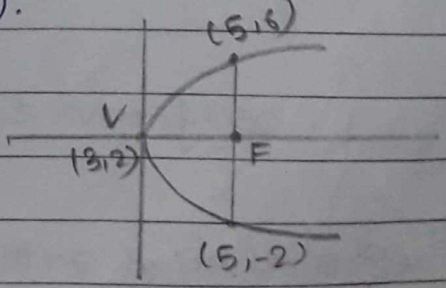
∴ The required eqⁿ of parabola is $y^2 = -4 \times 4 (x+2)$

$y^2 = -16x + 32)$

∴ $y^2 + 16x - 32 = 0$

d) vertex (3,2), and end of latus rectum (5,6) and (5,-2).

→ Solution:



Mid point of latus rectum is Focus. so

Mid-point $= \frac{x_1+x_2}{2}, \frac{y_2+y_1}{2}$

$= \frac{5+5}{2}, \frac{6-2}{2}$

$= 5, 2$

Focus (5,2) vertex (3,2)

Since y-coordinate of the vertex and focus are equal. so the axis is parall to x-axis,

$x = Sa$ $(x-h)^2 = 4a(y-k)$

here $(h,k) = (3,2)$

$y = Sa$ $(y-k)^2 = 4a(x-h)$

and $(h+a,k) = (5,2)$

$\therefore h+a = 5$

$a = 5-3 = 2$

Now,

eq^n of parabola is

$(y-2)^2 = 4a(x-3)$

$y^2 - 4y + 4 = 4\times2(x-3)$

$y^2 - 4y + 4 = 8x - 24$

$\boxed{y^2 - 4y - 8x + 28 = 0}$

which is req. eq^n of parabola.

1. Verify Rolle's theorem for the function $f(x) = \frac{x^3}{3} - 3x$ on iterval $[-3, 3]$.

→ Solution:

Given function $(f(x)$ is polynomial function which exist for all $x \in [-3,3]$

so it is continuous.

$f'(x) = \frac{1}{\cancel{3}} \times \cancel{3}x^2 - 3$

$\therefore f'(x) = x^2 - 3$

So it is differentiable at open interval $x \in (-3,3)$

then,

$f(a) = f(-3) = \frac{-3^3}{3} + 3 \times 3 = -9 + 9 = +0$

$f(b) = f(3) = \frac{3^3}{3} - 9 = +9 - 9 = 0$

$\therefore f(a) = f(b) = 0$

then,

there exists at least a point $c \in (-3,3)$, such that

$f'(c) = 0$

$c^2 - 3 = 0$

$\therefore c^2 = 3$

$\therefore c = \sqrt{3}$

$\therefore c = 1.73 \in (-3, 3)$

Hence Rolle's theorum is verified.

2. Find the eccentricity of the hyperbola $9x^2 - 16y^2 = 144$

→ Solution,

$9x^2 - 16y^2 = 144$

or, $\frac{9x^2}{144} - \frac{16y^2}{144} = 1$

or $\frac{x^2}{16} - \frac{y^2}{9} = 1$

Compairing $\frac{x^2}{(4)^2} - \frac{y^2}{(3)^2} = 1$ with $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$

$\therefore a = 4 \;,\; b = 3$

Now,

we have,

eccentricity of hyperbola $= \sqrt{1 + \frac{b^2}{a^2}}$

$\therefore e = \sqrt{1 + \frac{9}{16}} = \sqrt{\frac{16+9}{16}}$

$e = \sqrt{\frac{25}{16}} = \frac{5}{4}$

$\therefore$ eccentricity of hyperbola is $\frac{5}{4}$.

3. Find the area enclosed by the curve $r^2 = 4\cos 2\theta$

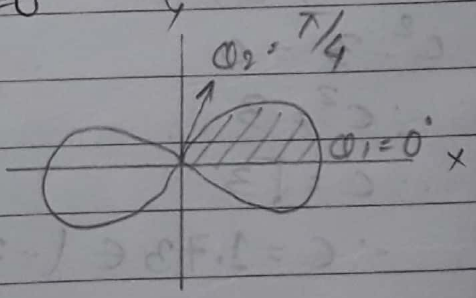
→ Solution,

$r^2 = 4\cos 2\theta$

we have,

Area of curve $= \int_{\theta_1 = 0}^{\theta = \pi/4} \frac{1}{2} r^2 \, d\theta$

$= \int_{0^\circ}^{\pi/4} \frac{1}{\cancel{2}} \cancel{4} \cos 2\theta$



$= 2\int_0^{\pi/4} \cos 2\theta$

$= 2\left[\frac{\sin 2\theta}{2}\right]_0^{\pi/4}$

$= 2 \times \left[\frac{\sin \cancel{2} \cdot \frac{\pi}{\cancel{4}2}}{2} - \frac{\sin 2 \cdot 0^\circ}{2}\right]$

$= 2 \times \left[\frac{1}{2} - \frac{0}{2}\right]$

$= 1$ sq. unit

∴ The total area enclosed by curve = 1×4 = 4 sq. unit.

* Find the length of indicated portion of curve:

ⓐ $r(t) = (2\cos t)\vec{i} + (2\sin t)\vec{j} + \sqrt{5}t\,\vec{k}$, $0 \le t \le \pi$

→ Solution,

we have, $\text{Length}(L) = \int_0^\pi |v|\,dt$

$$v = \frac{dr}{dt} = (-2\sin t)\vec{i} + (2\cos t)\vec{j} + \sqrt{5}\,\vec{k}$$

$$|v| = \sqrt{(-2\sin t)^2 + (2\cos t)^2 + (\sqrt{5})^2}$$
$$= \sqrt{4(\sin^2 t + \cos^2 t) + 5}$$
$$= \sqrt{9} = 3$$

$$\therefore L = \int_0^\pi 3\,dt = 3\,[t]_0^\pi = 3\pi \ \#$$

∴ Required length is 3π unit.

ⓑ $r(t) = (6\sin 2t)\vec{i} + (6\cos 2t)\vec{j} + 5t\,\vec{k}$, $0 \le t \le \pi$

→ Solution,

we have, $L = \int_0^\pi |v|\,dt$

$$v = \frac{dr}{dt} = (6 \times 2\cos 2t)\vec{i} + (-6 \cdot 2\sin 2t)\vec{j} + 5\vec{k}$$
$$= (12\cos 2t)\vec{i} + (-12\sin 2t)\vec{j} + 5\vec{k}$$

$$|v| = \sqrt{144\cos^2 2t + 144\sin^2 2t + 25}$$
$$= \sqrt{144 + 25} = \sqrt{169} = 13$$

$$\therefore L = \int_0^\pi 13\,dt$$
$$= 13\,[t]_0^\pi$$
$$= 13\pi \text{ Unit}$$

∴ Required length of curve is 13π unit #

ⓒ $r(t) = t\vec{i} + \frac{2}{3}t^{3/2}\vec{k}$, $0 \le t \le 8$.

→ Solution,

$$\text{length } (L) = \int_0^8 |v|\, d\cdot t$$

$$v = \frac{dr}{dt} = \vec{i} + \frac{2}{3} \times \frac{3}{2} t^{3/2-1}\vec{k}$$

$$= \vec{i} + t^{1/2}\vec{k}$$

$$|v| = \sqrt{(1)^2 + (t^{1/2})^2} = (1+t)^{1/2}$$

$$\therefore \text{Length} = \int_0^8 (1+t)^{1/2}\, dt =$$

$$= \left[\frac{[1+t]^{1/2+1}}{(1/2+1)\times 1}\right]_0^8$$

$$= \frac{2}{3}\left[\left[1+t\right]^{3/2}\right]_0^8$$

$$= \frac{2}{3}\left\{(9)^{3/2} - (1)^{3/2}\right\}$$

$$= \frac{2}{3}\left\{3^{2 \cdot 3/2} - 1\right\}$$

$$= \frac{2}{3}(27-1)$$

$$= \frac{2\times 26}{3}$$

$$|v| = \sqrt{1 + t^{1/2 \times 2}}$$

$$\text{Length} = \int_0^{\pi/2} |v|\, dt$$

$$v = \frac{dr}{dt} = \frac{d\cos^3 t}{d\cos t} \times \frac{d\cos t}{dt}$$

$$= 3\cos^2 t\,(-\sin t)$$

$$v = \frac{dr}{dt} = \frac{d(\cos^3 t)}{dt}\vec{j} + \frac{d(\sin^3 t)}{dt}\vec{j}$$

$$= 3\cos^2 t \cdot (-\sin t)\vec{j} + 3\sin^2 t \cdot \cos t\,\vec{j}$$

$$|v| = \sqrt{9\cos^4 t \cdot \sin^2 t + 9\sin^4 t \cdot \cos^2 t}$$

$$= \sqrt{9\cos^2 t \cdot \sin^2 t\,(\cos^2 t + \sin^2 t)}$$

$$= 3\sin t \cdot \cos t$$

$$= \frac{3}{2}\,2\sin t \cdot \cos t$$

$$= \frac{3}{2}\sin 2t$$

$$L = \int_0^{\pi/2} \frac{3}{2}\sin 2t$$

$$= \frac{3}{2}\left[-\frac{\cos 2t}{2}\right]_0^{\pi/2}$$

$$= \frac{3}{4}\left[-\cos .\, 2.\pi/2 + \cos 2.0\right]$$

$$= \frac{3}{4}(\cancel{-}-1+1)$$

$$= \frac{3}{4} \times 2$$

$$v = \frac{dr}{dt} = \vec{i} + \frac{\sqrt{6}}{2} \times 2t\,\vec{j} + 3t^2\,\vec{k}$$

$|V| = \sqrt{1+6t^2+9t^4} = \sqrt{(1)^2+2.1.3t^2+(3t^2)^2}$

$= \sqrt{(1+3t^2)^2} \quad = (1+3t^2)$

$L = \int_{-1}^{1} (1+3t^2)\,dt$

$= [t]_{-1}^{1} + 3\left[\frac{t^3}{3}\right]_{-1}^{1} = [1-(-1)] + \frac{3}{3}[1^3-(-1)^3]$

$= (1+1)+(1+1) = 2+2 = 4$ unit.

∴ Required length of cure is 4 unit.

$V = \frac{dr}{dt} = (-a\sin t)\vec{i} + a\cos t\,\vec{j}$

$|V| = \sqrt{a^2\sin^2 t + a^2\cos^2 t} = \sqrt{a^2} = a$

Again,

Unit Vector $(T) = \frac{V}{|V|} = \frac{(-\cancel{a}\sin t)}{\cancel{a}}\vec{i} + \frac{\cancel{a}\cos t}{\cancel{a}}\vec{j}$

$= -\sin t\,\vec{i} + \cos t\,\vec{j}$

Again,

Curvature $(k) = \frac{1}{|v|}\left|\frac{dT}{dt}\right|$

$$\frac{dT}{dt} = -\cos t\,\vec{i} - \sin t\,\vec{j}$$

$$\left|\frac{dT}{dt}\right| = \sqrt{\cos^2 t + \sin^2 t} = 1$$

$$\therefore k = \frac{1}{|v|}\left|\frac{dT}{dt}\right| = \frac{1}{a} \times 1 = 1/a$$

Unit tangent Vector $(T) = \frac{v}{|v|} = \frac{(-a\sin t)\vec{i} + (a\cos t)\vec{j} + b\vec{k}}{\sqrt{a^2+b^2}}$

$$\frac{dT}{dt} = \frac{(-a\cos t)\vec{i} - (a\sin t)\vec{j} + 0}{\sqrt{a^2+b^2}}$$

$$|v \times a| = \sqrt{144\cos^2 t + 144\sin^2 t + 81}$$

$$= \sqrt{144(\cos^2 t + \sin^2 t) + 81} = \sqrt{225} = 15$$

$$|v| = \sqrt{9\cos^2 t + 9\sin^2 t + 25} = \sqrt{9+25} = \sqrt{25} = 5$$

Infinite Series:

Expression in the form of

$a_1 + a_2 + a_3 + \ldots\ldots + a_n + \ldots\ldots$ is called infinite series, where,

a_n is n^{th} term of infinite series.

Sequence form;

$S_1 = a_1$

$S_2 = a_2 + a_1$

$S_3 = a_1 + a_2 + a_3$

$\vdots$

$S_n = a_1 + a_2 + a_3 + \ldots\ldots + a_n$

$$\boxed{\therefore S_n = \sum_{n=1}^{n} a_n}$$ is a sequence of partial sum.

where,

S_n is a n^{th} partial sum.

Convergent Series:-

If the sequence of the partial sum of series converses to the certain value or limit, then this series is known as Convergent series.

$$a_1 + a_2 + a_3 + \ldots\ldots + a_n + \ldots\ldots = \sum_{n=1}^{\infty} a_n = L$$

or, $= \sum_{n=1}^{\infty} a_n = 0$, it is called divergent series.

Test:

i) Geometric series Test ii) Ratio test

iii) Root Test iv) limit Comparison test

v) Integral test.

* Geometric Series test :-

$a + ar + ar^2 + \ldots\ldots + ar^{n-1} + \ldots\ldots$

Common ratio $(r) = \frac{t_2}{t_1} = \frac{ar}{a} = r$

when,

$|r| < 1$

then the series converges to $S_\infty = \frac{a}{1-r}$

$|r| > 1$ or infinite,

then the series is diverges.

Q. Test whether the given series are convergent or divergent.

1.> $\sum_{n=0}^{\infty} \frac{(-1)^n}{4^n}$

→ Solution,

series $= 1 - \frac{1}{4} + \frac{1}{4^2} - \ldots\ldots + \infty$

common ratio $(r) = \frac{t_2}{t_1} = -\frac{\frac{1}{4}}{1} = -\frac{1}{4}$

$|r| = \frac{1}{4} < 1$, so series is converged.

Sum of series $(S_\infty) = \frac{a}{1+\frac{1}{4}} = \frac{4}{5} = 0.8$

2.> $\sum_{n=1}^{\infty} \frac{7}{4^n}$

→ series = ~~7x~~ $\frac{7}{4} + \frac{7}{4^2} + \frac{7}{4^3} + \ldots + \infty$

∴ common diff $(r) = \frac{t_2}{t_1} = \frac{\cancel{7}}{4^2} \times \frac{4}{\cancel{7}} = \frac{1}{4}$

$|r| = \frac{1}{4} < 1$, So it is convergent

sum $(S_\infty) = \frac{a}{1-r}$

$= \frac{1}{1-\frac{1}{4}}$

$= \frac{7}{\cancel{4}} \times \frac{\cancel{4}}{3} = \frac{7}{3}$ #.

3) $\sum_{n=0}^{\infty} (-1)^n \frac{5}{4^n}$

→ Series $= +5 - \frac{5}{4} + \frac{5}{4^2} + \dots + \infty$

$r = \frac{t_2}{t_1} = -\frac{5}{4} \times \frac{1}{\cancel{5}} = -\frac{1}{4}$

$|r| = \frac{1}{4} < 1$, so it is convergent

Sum of series $(S_\infty) = \frac{a}{1-r} = \frac{5}{1+\frac{1}{4}} = \frac{5}{1} \times \frac{4}{\cancel{5}} = 4$ #.

4) $\sum_{n=1}^{\infty} 9^{-n+2} . 4^{n+1}$

→ Series $= 9.4^2 + 9^0.4^3 + 9^{-1}.4^4 + \dots + \infty$

$r = \frac{t_2}{t_1} = \frac{64}{144} = 0.44$

$\therefore |r| = 0.44 < 1.$

So, it is convergent, Sum $= \frac{a}{1-r} = \frac{144}{1-0.44} = \frac{144}{0.56} = 259.2$

5) $\sum_{n=6}^{\infty} (-1)^n \left(\frac{2^{n+3}}{3^n}\right)$

→ series $= \frac{2^9}{3^6} - \frac{2^{10}}{3^7} + \frac{2^{11}}{3^8} \dots \infty$

$|r| = \left|\frac{t_2}{t_1}\right| = \left| -\frac{2^{10}}{3^7} \times \frac{3^6}{2^9} \right| = \frac{2^{10-9}}{3^{7-6}} = \frac{2}{3} = 0.66$

$= \frac{746496}{1119744}$

$|r| < 1$, so converged.

$S_\infty = \frac{a}{1-r} = \frac{0.702}{1+0.66} = 0.42$ #.

6. $\sum_{n=1}^{\infty} \frac{2^{n+1}+9^{n+2}}{5^n}$

→ series $= \frac{2^2+9^3}{5} + \frac{5^3+9^4}{5^2} + \frac{5^4+9^5}{5^3} + \dots\dots$

$a = \frac{2^2+9^3}{5} = 146.6$

$r = \frac{t_2}{t_1} = \frac{267.44}{146.6} = 1.82$

$|r| > 1$, so it is divergent.

7-> $\sum_{n=0}^{\infty} \left(\frac{1}{2^n} + \frac{(-1)^n}{5^n} \right)$

$= \sum_{n=0}^{\infty} \left(\frac{1}{2^n} \right) + \sum_{n=0}^{\infty} \frac{(-1)^n}{5^n}$

$= \left(1 + \frac{1}{2} + \frac{1}{2^2} + \dots \right) + \left(1 - \frac{1}{5} + \frac{1}{5^2} - \dots \right)$

~~&~~ Common difference $(r_1) = \frac{1}{2} \times 1 = \frac{1}{2}$

Common diff. $(r_2) = -\frac{1}{5} \times 1 = -\frac{1}{5}$

$|r_1| =< 1$, so it is converged.

$|r_2| < 1$, so it is also converged

Sum(~~&~~ $S_{\infty 1}$) $= \frac{a_1}{1-r_1} = \frac{1}{1-\frac{1}{2}} = \frac{1}{1} \times \frac{2}{1} = 2$

Sum $(S_{\infty 2}) = \frac{a_1}{1-r_2} = \frac{1}{1+\frac{1}{5}} = \frac{1}{1.2} = 0.83$

$\therefore$ Sum $(S_\infty) = 2 + 0.83 = 2.83$

8-> $\sum_{n=0}^{\infty} \frac{(-4)^{3n}}{5^{n-1}}$.

$$\text{Series} = 1 - \frac{64}{1} + \frac{4096}{5} + \cdots \infty$$

$r = \frac{-64}{1} = -64$ $|r| = 64 > 1$, so it is divergent.

9. $$\sum_{n=1}^{\infty} \frac{3^{n-1} - ~~8~~ 1}{6^{n-1}}$$

→ solution,

$$\sum_{n=1}^{\infty} \left(\frac{3^{n-1}}{6^{n-1}} - \frac{1}{6^{n-1}} \right)$$

$$= \sum_{n=1}^{\infty} \left(\frac{1}{2^{n-1}} \right) - \sum_{n=1}^{\infty} \frac{1}{6^{n-1}}$$

$$= \left(1 + \frac{1}{2} + \frac{1}{2^2} + \cdots \right) - \left(1 + \frac{1}{6} + \frac{1}{6^2} + \cdots \right)$$

Common diff $(r_1) = \frac{1}{2}$ $\therefore |r| < 1$, so,
Common diff$(r_2) = \frac{1}{6}$ $|r| < 1$, they are convergent

$$\text{Sum}(S_{\infty_1}) = \frac{a_1}{1 - r_1} = \frac{1}{1 - 1/2} = 2$$

$$\text{Sum}(S_{\infty_2}) = \frac{a_1}{1 - r_2} = \frac{1}{1 - 1/6} = \cancel{1/2} \; \frac{1}{1} \times \frac{6}{5} = 1.2$$

$$\therefore \text{Sum}(S_\infty) = 2 - 1.2 = 0.8 \#$$

* Ratio Test :-

Let $\sum a_n$ be series with positive terms such that,

$$\boxed{\lim_{n \to \infty} \frac{a_{n+1}}{a_n} = L}$$

then,

a) If $L < 1$, then convergent series
b) If $L > 1$ or ∞, then divergent series.
c) If $L = 1$, then test is inconclusive

Note: When the question is in factorial form, then Use ratio test. n!....

* Investigate the convergence of following series.

a) $\sum_{n=0}^{\infty} \frac{2^n+5}{3^n}$

→ Solution,

Given that, $a_n = \frac{2^n+5}{3^n}$

$a_{n+1} = \frac{2^{n+1}+5}{3^{n+1}}$

Now,

$$L = \lim_{n\to\infty} \frac{a_{n+1}}{a_n} = \lim_{n\to\infty} \frac{2^{n+1}+5}{3^{n+1}} \Big/ \frac{2^n+5}{3^n}$$

$$\text{so, } L = \lim_{n\to\infty} \frac{2^n.2+5}{\cancel{3^n}.3} \times \frac{\cancel{3^n}}{2^n+5}$$

$$\text{so, } L = \lim_{n\to\infty} \frac{\cancel{2^n}(2+\frac{5}{2^n})}{3.\cancel{2^n}(1+\frac{5}{2^n})}$$

take n common now as you can take n common always

$$\text{so } L = \frac{(2+\frac{5}{\infty})}{3(1+\frac{5}{\infty})}$$

$[\infty + 1 = 0]$

$[n^\infty = 0]$

$2^n = 2^\infty = \infty$

$\frac{1}{\infty} = 0$

$$\text{so, } L = \frac{2}{3}$$

$\therefore L < 1$, so it is Convergent.

b) $\sum_{n=1}^{\infty} \frac{a^n}{n!}$

→ Given, $a_n = \frac{a^n}{n!}$ $a_{n+1} = \frac{a^{n+1}}{(n+1)!}$

$n! = n\,(n-1)\,(n-2)!$

$[\infty + 1 = \infty]$ $\quad \frac{1}{\infty} = 0$

Now,

$$L = \lim_{n\to\infty} \frac{a_{n+1}}{a_n} = \frac{a^{n+1}}{(n+1)!} \times \frac{n!}{a_n} = \frac{\cancel{a^n}\cdot a}{(n+1)\,\cancel{n!}} \times \frac{\cancel{n!}}{\cancel{a^n}}$$

$$\text{or, } L = \lim_{n\to\infty} \frac{a}{n+1}$$

$$\text{or, } L = \frac{a}{0} = 0 < 1,$$

So it is convergent.

3. $$\sum_{n=1}^{\infty} \frac{4^n\, n!\, n!}{(2n)!}$$

→ $a_n = \frac{4^n\, n!\, n!}{(2n)!}$, $a_{n+1} = \frac{4^{n+1}\,(n+1)!\,(n+1)!}{(2n+2)!}$

Now,

$$L = \lim_{n\to\infty} \frac{4^n\cdot 4\,(n+1)!\,(n+1)!}{(2n+2)!} \times \frac{(2n)!}{4^n\, n!\, n!}$$

$$= \lim_{n\to\infty} \frac{\cancel{4^n}\cdot 4\,(n+1)\,\cancel{n!}\,(n+1)\,\cancel{(n)!}}{(2n+2)\,(2n+1)\,\cancel{(2n)!}} \times \frac{\cancel{(2n)!}}{\cancel{4^n}\,\cancel{n!}\,\cancel{n!}}$$

$$= \lim_{n\to\infty} \frac{4\;\cancel{n}(1+1/n)\,\cancel{n}(1+1/n)}{\cancel{n}(2+2/n)\,\cancel{n}(2+1/n)}$$

$$= \frac{4\,(1+0)\,(1+0)}{(2+0)\,(2+0)}$$

$$= \frac{4}{4}$$

$$= 1$$

∴ $L = 1$, so it is inconclusive.

4. $$\sum_{n=1}^{\infty} \frac{n^2}{3^n}$$

→ Solution $a_n = \frac{n^2}{3^n}$, $a_{n+1} = \frac{(n+1)^2}{3^{(n+1)}}$

$$L = \lim_{n\to\infty} \frac{(n+1)^2}{3^{(n+1)}} \times \frac{3^n}{n^2}$$

$$= \lim_{n\to\infty} \frac{n^2+2n+1}{\cancel{3^n}.3} \times \frac{\cancel{3^n}}{n^2}$$

$$= \lim_{n\to\infty} \frac{1}{3}\left(\frac{n^2}{n^2}+\frac{2n}{n^2}+\frac{1}{n^2}\right)$$

$$= \lim_{n\to 0} \frac{1}{3}\left(1+\frac{2}{n}+\frac{1}{n^2}\right)$$

$= \frac{1}{3}(1+0+0) = L = \frac{1}{3} < 1$, so it is convergent.

5.> $\sum_{n=1}^{\infty} \frac{(2n)!}{n!n!}$

→ $a_n = \frac{(2n)!}{n!n!}$ $a_{n+1} = \frac{(2n+1)!}{(n+1)!(n+1)!}$

Now,

$$L = \lim_{n\to\infty} \frac{(2n+1)!}{(n+1)!(n+1)!} \times \frac{n!\,n!}{(2n)!}$$

$$= \lim_{n\to\infty} \frac{(2n+2)\cancel{(2n)!}(2n+1)}{(n+1)\cancel{n!}(n+1)\cancel{n!}} \times \frac{\cancel{n!\,n!}}{\cancel{(2n)!}}$$

$$= \lim_{n\to\infty} \frac{\cancel{n}(2+2/n)\cancel{n}(2+1/n)}{\cancel{n}(1+1/n)\cancel{n}(1+1/n)}$$

$= (2+0)\ (2+0)$

$= 4$

$\therefore L = 4 > 1$, so it is divergent.

6. $\sum_{n=1}^{\infty} \frac{n!}{n^n}$ (Formula : $\lim_{n\to\infty}\left(1+\frac{x}{n}\right)^{n} = e^x$)

→ $a_n = \frac{(n)!}{n^n}$, $a_{n+1} = \frac{(n+1)!}{(n+1)^{n+1}}$

$$= \lim_{n\to\infty} \left(\frac{n}{n+1}\right)^n$$

$$= \lim_{n\to\infty} \left[\frac{\cancel{n}}{\cancel{n}(1+1/n)}\right]^n$$

$$= \lim_{n\to\infty} \left(\frac{1}{(1+1/n)^n}\right) \qquad \left[\because \lim_{n\to\infty}\left(1+\frac{x}{n}\right)^{x} = e^x\right]$$

$$= \frac{1}{e}$$

7.) $\sum_{n=1}^{\infty} \frac{n\, 2^n (n+1)!}{3^n\, n!}$

→ $a_n = \frac{n\, 2^n (n+1)!}{3^n\, n!}$, $a_{n+1} = \frac{(n+1)\, 2^{n+1}\, (n+1+1)!}{3^{n+1}\, (n+1)!}$

Now

$$l = \lim_{n\to\infty} \frac{(n+1)\, \cancel{2^n}.\, 2\, (n+2)!}{\cancel{3^n}.\, 3\, (n+1)!} \times \frac{\cancel{3^n}\, n!}{n\, \cancel{2^n}.\, (n+1)!}$$

$$= \lim_{n\to\infty} \frac{(n+1)\; 2\, (n+2)\, \cancel{(n+1)!}}{3(n+1)\, \cancel{(n)!}} \times \frac{\cancel{n!}}{n\, \cancel{(n+1)!}}$$

$$= \lim_{n\to\infty} \frac{2}{3}\, \frac{\cancel{n}(1+1/n) \cdot \cancel{n}(1+2/n)}{\cancel{n}(1+1/n) \cdot \cancel{n}}$$

$$= \frac{2}{3}\, \frac{(1+0)\,(1+0)}{1+0}$$

$L = 2/3 < 1$, so it is Convergent.

$3! = 3\times 2\times 1 = 6$

8) $\sum_{n=1}^{\infty} \frac{(n+3)!}{3!.n!\,3^n}$

→ Solution

$a_n = \frac{(n+3)!}{3!.n!\,3^n}$, $a_{n+1} = \frac{(n+1+3)!}{3!\,(n+1)!\,3^{n+1}}$

$$L = \frac{a_{n+1}}{a_n} = \lim_{n\to\infty} \frac{(n+4)!}{\cancel{3!}(n+1)!\,\cancel{3^n}.3} \times \frac{\cancel{3!}\,n!\,\cancel{3^n}}{(n+3)!}$$

$$= \lim_{n\to\infty} \frac{(n+4)\,\cancel{(n+3)!}}{(n+1)\,\cancel{(n)!}\,3} \times \frac{\cancel{n!}}{\cancel{(n+3)!}}$$

$$= \lim_{n\to\infty} \frac{\cancel{n}(\cancel{a}\,1+\frac{4}{n})}{\cancel{n}(1+\frac{1}{n})\,3}$$

$$= \frac{1+0}{(1+0)3}$$

$\therefore L = \frac{1}{3} < 1$, so it is convergent.

Root Test:-

Let $\sum a_n$ be a series, such that,

$$\lim_{n\to\infty} \sqrt[n]{a_n} = L$$

$$\sqrt[n]{a_n} = (a_n)^{1/n}$$

$n^{1/n} = 1$

then,

a) if $L<1$, the series is convergent.

b) if $L>1$, or infinite, then series is divergent.

c) if $L=1$, then inconclusive.

Note:

if $\lim_{n\to\infty} \sqrt[n]{n} = n^{1/n} = 1$

$\lim_{n\to\infty} \left(1+\frac{x}{n}\right)^n = e^x$

$\lim_{n\to\infty} \frac{d(a)^x}{dx} = a^{\cancel{x}} \ln a$

Test the convergence of the following series.

1. $\sum_{n=1}^{\infty} \frac{n^2}{2^n}$

→ Solution, $a_n = \frac{n^2}{2^n}$

$$L = \lim_{n\to\infty} (a_n)^{1/n} = \lim_{n\to\infty} \left(\frac{n^2}{2^n}\right)^{1/n} = \lim_{n\to\infty} \left(\frac{n^2}{2^n}\right)^{1/n}$$

$$= \lim_{n\to\infty} \frac{\left((n)^{1/n}\right)^2}{2^{\cancel{n}\times 1/\cancel{n}}}$$

∴ $L = \frac{1}{2} < 1$, so it is convergent.

2. $\sum_{n=1}^{\infty} \frac{2^n}{n^2}$

→ Solution, $a_n = \frac{2^n}{n^2}$

$$\therefore L = \lim_{n\to\infty} (a_n)^{1/n} = \lim_{n\to\infty} \left(\frac{2^n}{n^2}\right)^{1/n} = \lim_{n\to\infty} \frac{2^{\cancel{n}\times 1/\cancel{n}}}{(n^{1/n})^2} = \frac{2}{1}$$

∴ $L = 2 > 1$, so it is divergent.

3. $\sum_{n=1}^{\infty} \left(\frac{1}{1+n}\right)^n$

→ Solution,

$$a_n = \left(\frac{1}{1+n}\right)^n$$

$$L = \lim_{n\to\infty} \left(\frac{1}{1+n}\right)^{\cancel{n}\times 1/\cancel{n}} = \frac{1}{1+\infty} = \frac{1}{\infty} = 0$$

∴ $L = 0 < 1$, so it is convergent.

4. $\sum_{n=1}^{\infty} \frac{n^{10}}{10^n}$

→ Solution;

$$L = \lim_{n\to\infty} \left(\frac{n^{10}}{10^n}\right)^{1/n}$$

$$= \lim_{n\to\infty} \frac{(n^{1/n})^{10}}{10^{n\times 1/n}}$$

$$= \frac{1^{10}}{10}$$

$\therefore L = \frac{1}{10} = 0.1 < 1$, so it is convergent.

5. $\sum_{n=1}^{\infty} \left(\frac{n}{3n+1}\right)^n$

→ $a_n = \left(\frac{n}{3n+1}\right)^n$

$$L = \lim_{n\to\infty} \left(\frac{n}{3n+1}\right)^{n\times 1/n} = \lim_{n\to\infty} \frac{n}{n(3+1/n)} = \frac{1}{3+0} = 1/3$$

$\therefore L = 1/3 < 1$. so it is convergent.

6. $\sum_{n=1}^{\infty} \left(1+\frac{1}{n}\right)^{-n^2}$

→ Solution, $a_n = \left(1+1/n\right)^{-n^2}$

$$L = \lim_{n\to\infty} \left(1+1/n\right)^{-n^2\times 1/n} \qquad \left[\therefore \left(1+\frac{x}{n}\right)^n = e^x\right]$$

$$= \lim_{n\to\infty} \left(1+1/n\right)^{-n}$$

$\therefore L = e^{-1} = 1/e = 0.36 < 1$, so it is convergent.

7. $\sum_{n=1}^{\infty} \left(\frac{n}{n+1}\right)^{n^2}$

$a_n = \left(\frac{n}{n+1}\right)^{n^2}$

$$L = \lim_{n\to\infty} \left(\frac{n}{n+1}\right)^{n^2\times 1/n}$$

or, ~~$L = \lim_{n\to 0} \left(\frac{n}{n} + \frac{n}{1}\right)^n$~~

~~$= \lim_{n\to 0} (1+$~~

or, $L = \lim_{n \to \infty} \left(\frac{n}{n(1+1/n)} \right)^n$

or $L = \lim_{n \to \infty} \frac{1}{(1+1/n)^n}$

or $L = \frac{1}{e} = 0.36 < 1$, So it is convergent.

8. $\sum_{n=1}^{\infty} \frac{n^n}{2^{n^2}}$ $\left[\frac{d(a^x)}{dx} = a^n \ln a \right]$

→ Solution, $a_n = \frac{n^n}{2^{n^2}}$

$\therefore L = \lim_{n \to \infty} \left(\frac{n}{2^n} \right)^{n \times 1/n} = \lim_{n \to \infty} \left(\frac{n}{2^n} \right)$

$= \lim_{n \to \infty} \frac{1}{2^n \ln 2}$ [∵ L' Hospited Rule]

$= \frac{1}{\infty}$

$\therefore L = 0 < 1$, So, it is convergent.

* Integral Test (P-Series Test) :-

$\int_{x=a}^{x=b} f(x) = dx$ = finite value ⇒ convergent series.

$\int_{x=a}^{x=b} f(x) = dx$ = infinite value ⇒ Divergent series.

P- series Test (P- Test) :-

$$\left(\sum_{n=1}^{\infty} \frac{1}{n^P} = \frac{1}{n} + \frac{1}{n^2} + \frac{1}{n^3} + \cdots\cdots \right)$$

$$\int_{x=1}^{x=\infty} \frac{1}{x^p}\,dx = \left[\frac{x^{-p+1}}{-p+1}\right]_1^\infty$$

x^{-1}

$x \quad = \frac{1}{x}$

$$= \lim_{a\to\infty}\left[\frac{x^{-p+1}}{-p+1}\right]_1^a$$

$$= \frac{1}{1-p}\lim_{a\to\infty}\left[x^{-p+1}\right]_1^a$$

when,

$p > 1$ let $p = 2$ $x^{-2+1} = x^{-1} = \frac{1}{x}$

$p > 1$

$$\lim_{a\to\infty} = \frac{1}{1-p}\left[\frac{1}{x^{p-1}}\right]_1^a$$

$$= \frac{1}{1-p}\lim_{a\to\infty}\left[\frac{1}{a^{p-1}} - \frac{1}{1^{p-1}}\right]$$

$$= \frac{1}{1-p}(0-1)$$

$$= \frac{1}{p-1} = (\text{finite})$$

Hence the Series is convergent.

Eg when $p > 1$.

$$\sum_{n=1}^{\infty}\frac{1}{n^2} = \frac{1}{1^2}+\frac{1}{2^2}+\frac{1}{3^2}+\dots$$ converged.

$p < 1$ ∞ ∞

when $p < 1$.

$$= \frac{1}{1-p}\lim_{a\to\infty}\left[x^{1-p}\right]_1^a$$ let $p = -1$ $x^{1+1} = x^{2}$

$$\boxed{\begin{array}{l} \infty + 1 = \infty \\ \infty - 1 = \infty \\ \infty \times 1 = \infty \\ \infty \div 1 = \infty \end{array}}$$

$$= \frac{1}{1-p}\lim_{a\to\infty}\left[a^{1-p} - 1^{1-p}\right]$$

$$= \frac{1}{1-p}\times\infty$$ $\frac{1}{\infty} = 0$

$= \infty$ divergent.

$$\sum_{n=1}^{\infty} \frac{1}{n^{1/2}} = \frac{1}{1^{1/2}} + \frac{1}{2^{1/2}} + \frac{1}{3^{1/2}} + \cdots\cdots$$

when $p = 1$ $\qquad p = 1$

$$= \frac{1}{1-p} \lim_{a\to\infty} \left[x^{1-p} \right]_1^a$$

$$= \frac{1}{1-p} \lim_{a\to\infty} \left[a^{1-p} - 1^{1-p} \right]$$

$$= \frac{1}{0} \left[a^{1-1} - 1^{1-1} \right]$$

$$= \infty \times 1$$

$$= \infty \quad \text{(divergent)}$$

e.g. $\displaystyle\sum_{n=1}^{\infty} 1/n = 1/1 + 1/2 + 1/3 + \cdots\cdots$

$\therefore$ Harmonic Series = divergent.

* P-Test by Integral Test

$$\sum_{n=1}^{\infty} \frac{1}{n^p} = \frac{1}{1^p} + \frac{1}{2^p} + \frac{1}{3^p} + \cdots\cdots$$

when $P > 1$, then series is convergent.

when $P \leq 1$, Then series is divergent

when $P = 1$, Then series is inconclusive.

$$\sum_{n=1}^{\infty} \frac{1}{n^{p=1}} = 1 + 1/2 + 1/3 + 1/4 + \cdots\cdots$$

Harmonic Series are always divergent.

$$\sum_{x=1}^{\infty} \frac{1}{x} dx = [\log x]_1^{\infty} = \log\infty - \log 1$$
$$= \infty$$

Harmonic Series is Divergent.

$\frac{1}{\infty} = 0.$

$$\sum_{n=1}^{\infty} \frac{1}{n}$$

→ Ratio Test, $a_n = \frac{1}{n}$, $a_{n+1} = \frac{1}{n+1}$

$$\lim_{n\to\infty} \frac{a_{n+1}}{a_n} = \lim_{n\to\infty} \left(\frac{1}{n+1}\right) \times \frac{n}{1} = \frac{\cancel{n}}{\cancel{n}(1+1/n)} = 1$$

∴ L = 1, so test is inconclusive.

example:- $\sum_{n=1}^{\infty} \frac{1}{n} = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \frac{1}{6} + \frac{1}{7} + \frac{1}{8} + \dots$

$1 + \frac{1}{2} = 1.5$ $\quad \frac{2}{4} = \frac{1}{2} = \frac{1}{3} + \frac{1}{4} = 0.58$ $\quad \frac{4}{8} = \frac{1}{2}$

$0.58 > \frac{2}{4} = \frac{1}{2}$ $\quad = 0.634 > \frac{4}{8} > \frac{1}{2}$

* Limit Comparison Test:

let $\sum a_n$ and $\sum b_n$ be series then

a) when $\lim_{n\to\infty} \frac{a_n}{b_n} = L > 0$, then series both converges or diverges.

b) when $\lim_{n\to\infty} \frac{a_n}{b_n} = \infty$, and $\sum b_n$ diverges then $\sum a_n$ also diverges.

to find bn compare power and put highest power n.

Questions:

a) $\sum_{n=1}^{\infty} \frac{2n+1}{n^2+2n+1}$.

→ Solution,

$a_n = \frac{2n+1}{n^2+2n+1}$, $b_n = \frac{2n}{n^2} = \frac{2}{n}$

$b_n = \frac{2}{n}$, P = 1, So by p-test bn is divergent.

Now, $\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{2n+1}{n^2+2n+1} \times \frac{n}{2} = \lim_{n\to\infty} \frac{n^{\cancel{2}}(2+1/n)}{n^2(1+2/n+1/n^2)2}$

$$= \frac{2 + \frac{1}{\infty}}{\left(1 + \frac{2}{\infty} + \frac{1}{\infty^2}\right) \times 2}$$

$$= \frac{2}{2} = 1$$

∴ a_n is also divergent series.

2> $\sum_{n=1}^{\infty} \frac{\sqrt{n}}{n^2+1}$

→ Solution, $a_n = \frac{\sqrt{n}}{n^2+1}$, $b_n = \frac{\sqrt{n}}{n^2}$

Now,

$$b_n = \frac{n^{1/2}}{n^2} = \frac{\cancel{8}\, 1}{n^{2-1/2}} = \frac{1}{n^{3/2}}$$

Since $P > 1$, so it is convergent by p-Test.

We have,

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\sqrt{n}}{n^2+1} \times \frac{n^2}{\sqrt{n}} = \frac{n^2}{n^2(1+\frac{1}{n^2})} = \frac{1}{1+0} = 1$$

∴ $L = 1 > 0$, so an also a convergent series.

4> $\sum_{n=1}^{\infty} \frac{n^4+5}{n^5}$

→ Solution, $a_n = \frac{n^4+5}{n^5}$, $b_n = \frac{n^4}{n^5} = \frac{1}{n}$

∴ $b_n = \frac{1}{n}$, $p = 1$, so it is divergent by P-test

Now,

$$\frac{a_n}{b_n} = \frac{n^4+5}{\cancel{n^5}} \times \frac{\cancel{n^5}}{n^4} = \lim_{n\to\infty} \frac{\cancel{n^4}\left(1+\frac{5}{n^4}\right)}{\cancel{n^4}} = 1 + 0 = 1$$

∴ $L = 1 > 0$, so it is also divergent series.

3.) $\sum_{n=1}^{\infty} \left(\sqrt{n^2+1} - n\right)$

→ $a_n = \sqrt{n^2+1} - n$

$= \frac{\sqrt{n^2+1} - n}{1} \times \frac{\sqrt{n^2+1}+n}{\sqrt{n^2+1}+n}$

$= \frac{(\sqrt{n^2+1})^2 - (n)^2}{\sqrt{n^2+1}+n}$

$= \frac{\cancel{n^2}+1-\cancel{n^2}}{\sqrt{n^2+1}+n}$

$\therefore a_n = \frac{1}{\sqrt{n^2+1}+n}$, $b_n = \frac{1}{n}$

∴ p = 1, so it is divergent from P-Test.

we know,

$\frac{a_n}{b_n} = \frac{1}{\sqrt{n^2+1}+n} \times \frac{n}{1}$

$\lim_{n\to\infty} = \frac{\cancel{n}}{\cancel{n}\left(\sqrt{1+1/n^2}+1\right)}$

$\lim_{n\to\infty} = \frac{1}{\sqrt{1+0}+1}$

$\therefore L = \frac{1}{2} = 0.5 \neq 0$

So it is also divergent series.

5.) $\sum_{n=1}^{\infty} \frac{2n-1}{n(n+1)(n+2)}$

→ Solution, $a_n = \frac{2n-1}{n(n+1)(n+2)}$

$= \frac{2n-1}{n^2(n+2)+n(n+2)}$ $= \frac{2n-1}{n^3+2n^2+n^2+2n}$

$= \frac{2n-1}{n^3+3n^2+2n}$

$\therefore b_n = \frac{2n}{n^3} = \frac{2}{n^2}$

$\because P > 1$, so it is convergent series by P-test.

Now,

$\frac{a_n}{b_n} = \lim_{n\to\infty} \frac{(2n-1)}{n^3+3n^2+2n} \times \frac{n^2}{2}$

$= \lim_{n\to\infty} \frac{\cancel{n^3}(2-\frac{1}{n^3})}{\cancel{n^3}(1+\frac{3}{n}+\frac{2}{n^2})2} = \lim_{n\to\infty} \frac{2-\frac{1}{n^3}}{2(1+\frac{3}{n}+\frac{2}{n^2})} = \frac{2}{2} = 1$

$l > 0$. / $\because l = 1$, so a_n is also convergent series

6. $\sum_{n=1}^{\infty} \frac{1}{2\sqrt{n}+1}$.

→ $a_n = \frac{1}{2\sqrt{n}+1}$, $b_n = \frac{1}{2\sqrt{n}} = \frac{1}{2n^{1/2}}$

$\because P < 1$, so it is divergent by P-test.

Now,

$\frac{a_n}{b_n} = \frac{1}{2\sqrt{n}+1} \times \frac{2\sqrt{n}}{1} = \frac{\cancel{\sqrt{n}}(2)}{\cancel{\sqrt{n}}(2+\frac{1}{\sqrt{n}})} = \frac{2}{2+0} = 1$

$\therefore L > 0$, so a_n also a divergent series.

7. $\sum_{n=1}^{\infty} \tan(\frac{1}{n})$

→ Solution, $a_n = \tan(\frac{1}{n})$, $b_n = \frac{1}{n}$

$b_n = \frac{1}{n} = P = 1$, so it is divergent series.

Now,

$\frac{a_n}{b_n} = \lim_{n\to\infty} \frac{\tan(\frac{1}{n})}{(\frac{1}{n})} = \lim_{n\to\infty} \frac{\sec^2(\frac{1}{n})\cancel{(-\frac{1}{n^2})}}{\cancel{(-\frac{1}{n^2})}}$

[L-Hospital Rule]

$= \sec^2(0) = \frac{1}{\cos^2 0} = 1 > 0$

So it is also divergent Series.

8.) $\sum_{n=1}^{\infty} \frac{1}{2^{n-1}}$

→ Solution, $a_n = \frac{1}{2^{n-1}}$, $b_n = \frac{1}{2^n}$

For bn, using root test

$b_n = \frac{1}{2^n} = \left(\frac{1}{2^n}\right)^{1/n} = \left(\frac{1}{2}\right)^{n \times 1/n} = \frac{1}{2} = 0.5$

∴ L = 0.5 < 1, so it is convergent series.

Now,

$\frac{a_n}{b_n} = \lim_{n\to\infty} \frac{1}{2^{n-1}} \times \frac{2^n}{1} = \frac{2^n}{2^n . 1} = 1$

So an is also convergent series.

n- term test for divergence:-

The necessary condition for the convergence of infinite series $\sum a_n$ is,

$\lim_{n\to\infty} a_n = 0$

but this is not sufficient.

Exception:-

$\sum_{n=1}^{\infty} \frac{1}{n}$ = divergent Series

$\lim_{n\to\infty} \frac{1}{n} = 0$ Convergent

* Questions:- $\because \lim_{n\to\infty}\left(1+\frac{x}{n}\right)^n = e^x$

a) $\sum_{n=1}^{\infty} n^2 = \lim_{n\to\infty} n^2 = \infty$, so it is divergent.

b) $\sum_{n=1}^{\infty} \frac{n+1}{n} = \lim_{n\to\infty} \frac{\cancel{n}(1+1/n)}{\cancel{n}(1)} = \lim_{n\to\infty} 1+\frac{1}{n} = 1$, Divergent.

c) $\sum_{n=1}^{\infty} \frac{-n}{2n+5} = \lim_{n\to\infty} \frac{-\cancel{n}}{\cancel{n}(2+5/n)} = -1/2$, Divergent.

d) $\sum_{n=1}^{\infty} \left(1+\frac{1}{2n}\right)^n = \lim_{n\to\infty}\left[\left(1+\frac{1}{2n}\right)^{2n}\right]^{\frac{1}{2}} = e^{1\cdot\frac{1}{2}} = 1.64 \neq 0$ Divergent.

Alternating Series:-

when, $n = 1, 2, 3 \dots.$

1. $\sum_{n=1}^{\infty} (-1)^{n+1} a_n = a_1 - a_2 + a_3 - a_4 + \dots.$

$\sum_{n=1}^{\infty} (-1)^n a_n = -a_1 + a_2 - a_3 + a_4 - \dots.$

2. $a_1 > a_2 > a_3 > \dots$ decreasing Orders.

3. Alternating series test:- [Leibniz Test]

* Questions:-

$\sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n} = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$

i.e. $a > a_2 > a_3 > \dots$
and also in $(+, -, +, -)$ alternative sign

* Leibniz Test:-

$\lim_{n\to\infty} \frac{1}{n} = 0$, Convergent series.

* Absolute Convergent:-

A Series $\sum_{n=1}^{\infty} a_n$ converges absolutely of the corresponding series of $\sum |a_n|$ converges.

* $1 - \frac{1}{2^2} + \frac{1}{3^3} - \frac{1}{4^4} + \dots = \sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n^2}$

Leibniz Test:-

$\lim_{n\to\infty} \frac{1}{n^2} = 0$, convergent.

Absolute Convergent:-

$\sum_{n=1}^{\infty} \left|(-1)^{n+1} \frac{1}{n^2}\right| = 1 + \frac{1}{2^2} + \frac{1}{3^3} + \frac{1}{4^4} + \dots$

$\sum_{n=1}^{\infty} |a_n| = \frac{1}{n^2}$ (if Leibniz & absol. come con & div/alter then series is Cond. Converged)

$\therefore$ by P test, $P > 1$, so convergent.

So the series is absolutely convergent.

* Conditional Convergent:-

a> $\sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n} = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots$

$\therefore \sum |a_n| = \sum \left|\frac{1}{n}\right|$, by P-test, $P = 1$, So series is divergent

Leibniz Test:-

$\lim_{n\to\infty} \frac{1}{n} = 0$, so Convergent

$P = 1$

∴ Series is Conditional Convergent.

* $\sum_{n=1}^{\infty} (-1)^{n+1} \frac{1}{n^3}$

$\Rightarrow 1 - \frac{1}{2^3} + \frac{1}{3^3} - \frac{1}{4^3} + \cdots\cdots + \frac{1}{n^3} + \cdots\cdots$

Leibniz Test:

$\lim_{n\to\infty} \frac{1}{n^3} = 0$, so Series is Convergent by This test.

Absolute Value:

$\sum_{n=1}^{\infty} \left| (-1)^{n+1} \frac{1}{n^3} \right| = 1 + \frac{1}{2^3} + \frac{1}{3^3} + \frac{1}{4^3} + \cdots$

$\sum |a_n| = \sum \left| \frac{1}{n^3} \right|$,

Since $P > 1$, So Convergent.

Summary

i> Geometric series:-

If $|r| \geq 1$, then series diverges, otherwise it converges.

ii> For non-negative terms:-

Use integral test, ratio test, root test, and limit comparison test.

iii> Alternating series:-

Leibniz's test.

iv> n term test for divergence:-

Unless $a_n \to 0$

$\lim_{n\to\infty} a_n = 0$, convergent, otherwise divergent.

v> Series with absolute convergent:-

$\Sigma|a_n|$ = Convergent (Absolute Convergent)

Power Series:-

A series about $x=0$ in the form of,

$$\sum_{n=0}^{\infty} a_n x^n = a_0 + a_1 x + a_2 x^2 + a_3 x^3 + \cdots\cdots + a_n x^n + \cdots\cdots$$

is called power series.

At $x=a$

$$\sum_{n=0}^{\infty} a_n(x-a)^n = a_0 + a_1(x-a) + a_2(x-a)^2 + \cdots + a_n(x-a)^n + \cdots$$

where, a = Counter and $a_0, a_1, a_2, a_3, \ldots a_n$ = Coefficient / constant.

* Test the convergence for the given power series.

a> $$\sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^n}{n} = x - \frac{x^2}{2} + \frac{x^3}{3} - \cdots$$

→ $$\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = (-1)^{n-1+1} \frac{x^{n+1}}{n+1} \times \frac{n}{(-1)^{n-1} x^n}$$

$$= (-1)^n \frac{x^{n+1}}{n+1} \times \frac{n}{(-1)^{n-1} x^n}$$

$$= \cancel{(-1)^n} \frac{\cancel{x^n}\cdot x}{(n+1)} \times \frac{n}{\cancel{(-1)^n}\,(-1)^{-1}\,\cancel{x^n}}$$

$$= \left|\frac{n}{n+1}\cdot x\right| \qquad = \frac{n}{n(1+1/n)} = \frac{1}{1+0} = 1$$

$$= |x|$$

∴ $|x| < 1$, then converges absolutely.

∴ $|x| > 1$, then divergent.

b) $$\sum_{n=1}^{\infty} (-1)^{n-1} \frac{x^{2n-1}}{2n-1} = x - \frac{x^3}{3} + \frac{x^5}{5} - \cdots$$

→ Solution:

$$a_n = (-1)^{n-1} \frac{x^{2n-1}}{2n-1}, \quad a_{n+1} = (-1)^{n-1+1} \frac{x^{2(n+1)-1}}{(2(n+1)-1}$$

Now,

$$\lim_{n\to\infty} \left|\frac{a_{n+1}}{a_n}\right| = \frac{\cancel{(-1)^n}\, x^{2n+1}}{(2n+1)} \times \frac{(2n-1)}{\cancel{(-1)^n}\cdot(-1)^{-1}\cdot x^{2n-1}}$$

$$= \frac{\cancel{x^{2n}}\cdot x\,(2n-1)}{(2n+1)\,(-1)^{-1}\,\cancel{x^{2n}}\cdot x^{-1}}$$

$$= \frac{x^2(2n-1)}{(2n+1)}$$

$$= |x^2|$$

$|x^2| < 1$, converges absolutely

$|x^2| > 1$, then Divergent.

c) $$\sum_{n=0}^{\infty} \frac{x^n}{n!} = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots$$

→ $$a_{n+1} = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots = \frac{x^{n+1}}{(n+1)!}$$

Now,

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \cancel{x + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \ldots}$$

$$= \lim_{n\to\infty} \frac{x^{n+1}}{(n+1)!} \times \frac{n!}{x^n} = \frac{\cancel{x^n}\cdot x}{(n+1)\,\cancel{n!}} \times \frac{\cancel{n!}}{\cancel{x^n}} = \frac{x}{n+1}$$

for all value of x, it is zero. i.e. <1, so converges absolutely.

d.> $\sum_{n=0}^{\infty} n!\,x^n = 1 + x + 2!\,x^2 + x^3.3! + \ldots$

→ $a_{n+1} = (n+1)!\,x^{n+1}$, $a_n = n!\,x^n$

Now,

$$\lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right| = \frac{(n+1)\cancel{n!}\,\cancel{x^n}\cdot x}{\cancel{n!}\,\cancel{x^n}} = (n+1)\,|x|$$

Divergent for all values of x. exception case.

Fubini's Theorem :-

1) First Form :-

If $f(x,y)$ is continuous on region R :
$a \le x \le b$ and $c \le y \le d$, then

$$\iint_R f(x,y)\,dA = \int_{y=c}^{y=d}\int_{x=a}^{x=b} f(x,y)\,dx\,dy$$

$$= \int_{x=a}^{x=b}\int_{y=c}^{y=d} f(x,y)\,dy\,dx$$

This form gives the volume.

* evaluate :-

$f(x,y) = 1-6x^2y \quad , -1 \le x \le 1, \quad 0 \le y \le 2$

→ Solution

At first :- At second

$$\int_{y=0}^{2}\int_{x=1}^{1} (1-6x^2y)\,dx\,dy = \int_{x=-1}^{1}\int_{y=0}^{2} (1-6x^2y)\,dy\,dx$$

$$= \int_{0}^{2}\int_{-1}^{1} (1-6x^2y)\,dx\,dy$$

$$= \int_{0}^{2} \left[x - \frac{\overset{2}{\cancel{6}}x^3y}{\cancel{3}}\right]_{-1}^{1} dy$$

$$= \int_{0}^{2} \left[1-(-1) - \{2y - 2(-1)^3y\}\right] dy$$

$$= \int_{0}^{2} (2 - 2y - 2y)\,dy$$

$= \left[2y - \frac{4y^2}{2}\right]_0^2$

$= 2\times2 - 2(2)^2 - 0$

$= 4 - 8$

$= -4$

$\iiint_R dx\,dy\,dz$ = Volume

$\iint_R dx\,dy$ = Area

At second,

$\int_{-1}^{1}\int_{0}^{2} (1-6x^2y)\,dy\,dx$

$= \int_{-1}^{1} \left[y - \frac{\overset{3}{\cancel{6}}x^2y^2}{\cancel{2}}\right]_0^2 dx$

$= \int_{-1}^{1} \left[2 - 3x^2(2)^2\right] dx$

$= \int_{-1}^{1} \left[2 - 12x^2\right] dx$

$= \left[2x - \frac{\overset{4}{\cancel{12}}x^3}{\cancel{3}}\right]_{-1}^{1}$

$= \left[2x - 4x^3\right]_{-1}^{1}$

$= 2\times1 - 2\times(-1) - \{4\times(1)^3 - 4\times(-1)^3\}$

$= 2+2-(4+4)$

$= 4 - 8$

$= -4$

∴ Both $\int dy\,dx$ and $\int dx\,dy$ have same value.

$$\iint_R f(x,y)\,dA = \int_{y=a}^{y=b}\int_{x=g_1(y)}^{x=g_2(y)} f(x,y)\,dx\,dy$$

→ Solution

$y^2 = 4x$ ----(i)

$x^2 = 2y$

$y = \frac{x^2}{2}$ ---(ii)

solving eqn ① and ⑪, we get,

b) Triple integral $= \iiint_R dz\,dy\,dx$

* Find the Volume of region enclosed by Surface $z = x^2 + 3y^2$ and $z = 8 - x^2 - y^2$.

→ Sol^n,

STEP 1:- First find which is upper and lower limit in z.

for this, put the Value of x and y as 0.

then,

which is greater that is Upper & which value is lower that is lower limit.

i.e.

$z = 0^2 + 3 0^2 = 0 \rightarrow$ lower limit $= x^2 + 3y^2$

$z = 8 - 0^2 - 0^2 = 8 \rightarrow$ Upper limit $= 8 - x^2 - y^2$

STEP 2: To find limit of y,

Solve the equation as,

$x^2 + 3y^2 = 8 - x^2 - y^2$

or, $2x^2 + 4y^2 = 8$

or, $x^2 + 2y^2 = 4$ which is eq^n of ellipse

i.e. $\frac{x^2}{(2)^2} + \frac{y^2}{(\sqrt{2})^2} = 1$

∴ $a = 2$, $b = \sqrt{2}$

or, $2y^2 = 4 - x^2$

or, $y^2 = \frac{4 - x^2}{2}$

∴ $y = \pm\sqrt{\frac{4 - x^2}{2}}$

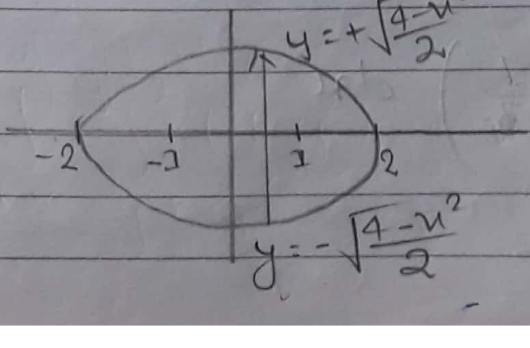
For y, Upper limit $= +\sqrt{\frac{4 - x^2}{2}}$

lower limit $= -\sqrt{\frac{4 - x^2}{2}}$

STEP 3: To find limit of x.

by solving,

eq^n is ellipse, i.e. $\frac{x^2}{(2)^2} + \frac{y^2}{(\sqrt{2})^2} = 1$



in this eq^n

$a = 2$

∴ Upper limit $= +2$

∴ lower limit $= -2$

Now,

$$\text{Volume} = \int_{x=-2}^{x=+2}\int_{y=-\sqrt{\frac{4-x^2}{2}}}^{y=+\sqrt{\frac{4-x^2}{2}}}\int_{z=x^2+3y^2}^{z=8-x^2-y^2} dz\,dy\,dx$$

Mass and First Moment formula

Mass :-

$$M = \iint_R \delta(x,y)\,dA$$

$[\therefore \delta(x,y)$ denotes density at $(x,y)]$

First Moments :-

$$M_x = \iint_R y\,\delta(x,y)\,dA$$

$$M_y = \iint_R x\,\delta(x,y)\,dA$$

Center of mass (centroid) $= \bar{x} = \dfrac{M_y}{M}$

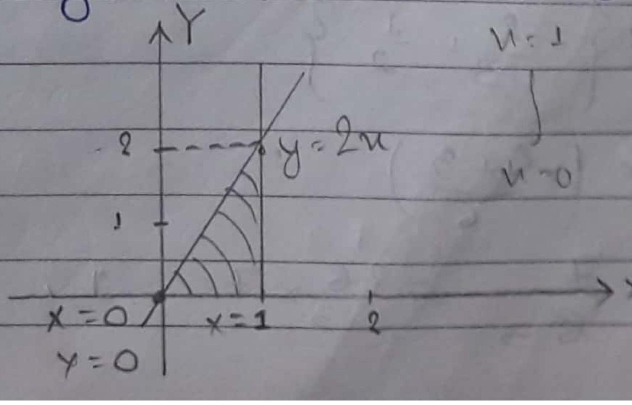
$$\bar{y} = \frac{M_x}{M}$$

* A thin plate covers the triangular Region bounded by the x-axis and the lines $x=1$, $y=2x$ in the first quadrant. The plate density at the point is $\delta(x,y) = 6x+6y+6$. Find the plate's mass, first moments and centroid (Centre of mass) about the co-ordinate axes).

→ from eqn $y=2x$

when $x=0, y=0$

$x=1, y=2$



$$\int_{x=0}^{x=1}\int_{y=0}^{y=2x} \delta(x,y)\,dy\,dx$$

$$= \int_{x=0}^{x=1}\int_{y=0}^{y=2x} \delta(x,y)\,dy\,dx$$

∴ we know mass $= \int_{x=0}^{x=1}\int_{y=0}^{y=2x} (6x+6y+6)\,dy\,dx.$

$$= \int_{x=0}^{x=1}\int_{y=0}^{y=2x} 6(x+y+1)\,dy\,dx$$

$$= 6\int_{0}^{1}\left[2x^2+\frac{4x^2}{2}+2x\right] dx$$

$$= 6\int_{0}^{1}\left[4x^2+2x\right] dx$$

Definition of Jacobian:-

- The Jacobian determinant or Jacobian of the co-ordinate transformation $x = g(u,v)$, $y = h(u,v)$ is,

$$J(u,v) = \begin{vmatrix} \frac{\delta x}{\delta u} & \frac{\delta x}{\delta v} \\ \frac{\delta y}{\delta u} & \frac{\delta y}{\delta v} \end{vmatrix} = \frac{\delta x}{\delta u}\frac{\delta y}{\delta v} - \frac{\delta y}{\delta u}\frac{\delta x}{\delta v}$$

The Jacobian is denoted by,

a, $x + \frac{\delta x}{\delta z}\left(z + \frac{y}{x} - 2x\right) = 0$

at point $(1,-1,-3)$

$$\frac{\delta x}{\delta z}\left(-3 + -\frac{1}{1} - 2\times 1\right) = -1$$

a. $\frac{\delta x}{\delta z} = \frac{-1}{(-3-1-2)} = \frac{\cancel{-}1}{\cancel{-}6} = 1/6$

Extreme Values And Saddle Points.

1. First derivative test :-

If a function $f(x,y)$ is continuous and differentiable.

$$\left.\begin{array}{l} f_x = 0 \\ f_y = 0 \end{array}\right\} \text{maximum or minimum.}$$

2. Second derivative test :-

If a function $f(x,y)$ is continuous and it's first and second derivative is differentiable at point (a,b) then;

a) If $f_{xx} > 0$ and $f_{xx} \cdot f_{yy} - f_{xy}^2 > 0$
Then function is minimum.

b) If $f_{xx} < 0$ and $f_{xx} \cdot f_{yy} - f_{xy}^2 > 0$, then the Function is maximum.

c) If $f_{xx} \cdot f_{yy} - f^2_{xy} < 0$, then there is saddle point.

d) If $f_{xx} \cdot f_{yy} - f^2_{xy} = 0$, then function is inconclusive.

* Find the extreme value of the following function :-

a) $f(x,y) = xy - x^2 - y^2 - 2x - 2y + 4.$

→ Solution :

The function is defined and differentiable for all x and y and its domain has no boundary points. The function therefore has extreme values only at the points where f_x and f_y are simultaneously zero. This leads to,

$f_x = \frac{\delta}{\delta x}(xy - x^2 - y^2 - 2x - 2y + 4)$ or,

for stationary point
$f_x = y - 2x - 2$
$f_y = x - 2y - 2$
$f_x = f_y = 0$

$\therefore f_x = y - 2x - 2 = 0$ --- (i)

$f_y = \frac{\delta}{\delta y}(xy - x^2 - y^2 - 2x - 2y + 4)$

$f_y = x - 2y - 2 = 0$ --- (ii)

$\therefore f_x = y - 2x - 2 = 0$

or, $y = 2x + 2$

Putting $y = 2x + 2$ in eqⁿ (ii)

$x - 2(2x + 2) - 2) = 0$

or, $x - 4x - 4 - 2 = 0$

or, $-3x = 6$

$\therefore x = -2$

$\therefore y = 2 \times (-2) + 2 = -2$

$\therefore (x, y) = (-2, +2)$

Now,

$f_{xx} = \frac{\delta}{\delta x}(y - 2x - 2) = -2$

$f_{yy} = \frac{\delta}{\delta y}(x - 2y - 2) = -2$

$f_{xy} = \frac{\delta}{\delta y}(y - 2x - 2) = 1$

$\therefore f_{xx} = -2 < 0$

$f_{xx} \cdot f_{yy} - f_{xy}^2 = (-2) \times (-2) - (1)^2 = 4 - 1$
$= 3 > 0$

Thus the function is maximum at (-2, -2). The value of f at f(-2,-2) is

$$f(-2,-2) = (-2)\times(-2) - (-2)^2 - (-2)^2 - 2\times(-2) - 2\times(-2) + 4$$
$$= 4 - 4 - 4 + 4 + 4 + 4$$
$$= 8 \#.$$

b.> $f(x,y) = 2xy - 5x^2 - 2y^2 + 4x + 4y - 4$

→ Solution :-

The function is defined and differentiable for all x and y and its domain has no boundary point. The function therefore has extereme values only at the point where fx and fy are simultaneously 0. This leads

$$f_x = 2y - 10x + 4 = 0 \quad \text{--- (i)}$$
$$f_y = 2x - 4y + 4 = 0 \quad \text{--- (ii)}$$
$$2y = 10x - 4$$
$$\therefore y = 5x - 2 \quad \text{--- (iii)}$$

put $y = 5x - 2$ in eqⁿ (ii)

$$2x - 4(5x - 2) + 4 = 0$$
$$\text{or, } 2x - 20x + 8 + 4 = 0$$
$$\text{or, } \cancel{-}18x = \cancel{-}12$$
$$\therefore x = \frac{12}{18} = \frac{2}{3}$$

Put $x = 2/3$ in eqⁿ (iii)

$$y = 5\times\frac{2}{3} - 2 = \frac{10}{3} - 2 = \frac{4}{3}$$

$$\therefore (x, y) = (2/3, 4/3)$$

Now,

$f_{xx} = -10$

$f_{yy} = -4$

$f_{xy} = 2$

Here,

$f_{xx} = -10 < 0$

and,

$f_{xx} \cdot f_{yy} - f_{xy}^2 = -10 \times -4 - (2)^2$

$= 40 - 4$

$= 36 > 0$

So the function f has local maximum at $(2/3, 4/3)$ (~~-10, -4~~) and it's value is,

$f(2/3, 4/3) = 2 \times \frac{2}{3} \times \frac{4}{3} - 5 \times \left(\frac{2}{3}\right)^2 - 2 \times \left(\frac{4}{3}\right)^2 * 4 \times \frac{2}{3} + 4 \times \frac{4}{3} - 4$

$= \frac{16}{9} - \frac{20}{9} - \frac{32}{9} + \frac{8}{3} \times \frac{3}{3} + \frac{16}{3} + \frac{3}{3} - \frac{4}{1} \times \frac{9}{9}$

$= \frac{16 - 20 - 32 + 24 + 48 - 36}{9}$

$= \frac{88 - 88}{9} = 0$

∴ The value of f at $f(2/3, 4/3)$ is 0 #.

b) $f(x, y) = 5xy - 7x^2 + 3x - 6y + 2$

→ Solution,

The function is defined and differentiable for all x and y. and its domain has no boundary point. The function therefore has the extreme value only at the point where f_x and f_y are simultaneously zero (0). This leads,

$f_x = 5y - 14x + 3 = 0$ --(i)

$f_y = 5x$ ~~$+1/3$~~ $- 6 = 0$ -(i) ∴ $x = \frac{6}{5}$

$5y - 14 \times \frac{6}{5} + 3 = 0$

or $5y = \frac{84}{5} - 3$

or $5y = \frac{69}{5}$

∴ $y = \frac{69}{25}$

$f_{xx} = \frac{\delta(5y-14x+3)}{\delta x} = -14$

$f_{yy} = \frac{\delta \overset{(5x-6)}{\cancel{(5y-14x+3)}}}{\delta y} = 0$

$f_{xy} = \frac{\delta(5y-14x+3)}{\delta y} = 5$

$f_{xx} = -14 < 0$

$f_{xx} \cdot f_{yy} - f_{xy}^2 = -14 \times 0 - 5^2 = 0 - 25 = -25 < 0$

Since $f_{xx} \cdot f_{yy} - f_{xy}^2 = -25 < 0$, so the function fxy has saddle point at $\left(6/5, \frac{69}{25}\right)$

c) $f(x,y) = x^2 + xy + 3x + 2y + 5$

→ Solution,

Given function is defined and differentiable for all x and y and its domain has no boundary point. The function therefore has extreme value only at point where fx and fy are simultaneously 0. This leads.

$f_x = \frac{\delta(x^2+xy+3x+2y+5)}{\delta x}$

$f_x = 2x+y+3 = 0$

$f_y = \frac{\delta(x^2+xy+3x+2y+5)}{\delta y}$

$f_y = x+2 = 0$ $\therefore x = -2$

then,

$2x+y+3 = 0$

or, $2(\times(-2)+y+3 = 0$

or, $-4+y+3 = 0$

$\therefore y = 1$ $\therefore (x,y) = (-2,1)$

Now,

$f_{xx} = \frac{\delta(2x+y+3)}{\delta x} = 2$

$f_{yy} = \frac{\delta(x+2)}{\delta y} = 0$

$f_{xy} = \frac{\delta(2x+y+3)}{\delta y} = 1$

Now, $\therefore f_{xx} = 2 > 0$

$f_{xx}\cdot f_{xy} - f_{xy}^2 = 2\times 0 - 1 = -1$

$\therefore -1 < 0$

$\therefore$ The function has Saddle point at $(-2,1)$.

d.) $f(x,y) = x^2+xy+y^2+3x-3y+4$

→ Solution,

given function is defined and differentiable for all x and y and its domain has no boundary point. The function therefore has extreme value only at point where f_x and f_y are simultaneously 0.

then,

$f_x = \frac{\delta(x^2+xy+y^2+3x-3y+4)}{\delta x}$

∴ $f_x = 2x+y+3 = 0$

$f_y = x+2y-3$

∴ $f_y = x+2y-3=0$

∴ $x = 3-2y$

Now,

$2x+y+3=0$

or, $2(3-2y)+y+3=0$

~~[illegible]~~ or, $6-4y+y+3=0$

or, $-3y+9=0$

or, $+3y=+9$

∴ $y=3$

put $y=3$ in $x=3-2y$

∴ $x = 3-2\times 3 = 3-6 = -3$

∴ $(x,y) = (-3,3)$

we know,

$f_{xx} = \frac{\delta(2x+y+3)}{\delta x} = 2$

$f_{xy} = \frac{\delta(2x+y+3)}{\delta y} = 1$

$f_{yy} = \frac{\delta(x+2y-3)}{\delta}$

∴ $f_{yy}=2$

Now,

$f_{xx}=2>0$

$f_{xx}\cdot f_{yy} - f_{xy}^2 = 2\times 2 - 1^2 = 3>0$

So the function f has local minimum at (-3,3) and its value at f(2,2) is

$f(2,2) = (2)^2+2\times2+(2)^2+3\times2-3\times2+4$

$f(-3,3) = 4+4+4+4 = 16$ ⋕.

e.> $f(x,y) = x^3+y^3+3x^2-3y^2-8$

→ Solution,

given function is defined and differentiable for all x and y and its domain has no boundary point. The function therefore has extreme value only at point where fx and fy are simultaneously zero. This leads,

$$f_x = \frac{\delta(x^3+y^3+3x^2-3y^2-8)}{\delta x}$$

$$= 3x^2+6x = 0$$

$$f_y = \frac{\delta(x^3+y^3+3x^2-3y^2-8)}{\delta y}$$

$$= 3y^2-6y = 0$$

$$f_x = 3x^2+6x = 0 \quad -- \text{(I)}$$

$$f_y = 3y^2-6y = 0 \quad -- \text{(II)}$$

$3x^2+6x=0$

Either $x=0,-2$

Eithe $y=0, y=2$

$\therefore x=(0,-2) \quad (y=0,2)$

$\therefore$ The points are $(0,0), (0,2)\ (-2,0), (-2,2)$

Now,

$f_{yy} = 6y-6$

ⓐ at point $(0,0)$

$$f_{xx}.f_{yy}-f_{xy}^2 = 6\times(-6)-0 = -36<0$$

$$f_{xx} = 6>0$$

then the function has saddte point at (0, 0).

$f_{yy} = 6y-6 = 6\times2-6 = 12-6 = 6$

$f_{xx} = 6 > 0$

$f_{xx}\cdot f_{yy} - f_{xy}^2 = 6\times6 - 0 = 36 > 0$

Hence the function have local minimum at (0,2) and its value is

$f_{xx} = -6 < 0$

$f_{xx}\cdot f_{yy} - f_{xy}^2 = -6\times-6-0 = +36 > 0$

Hence the function have local maximum at (−6,−6) and its value is,

$y = -5/2$

$\therefore$ Critical point $= (5, -5/2)$

$\therefore f(5,-5/2) = (5)^2 + 5\times(-5/2) + (-5/2)^2 - 6\times5 + 2$

$= 25 - \frac{25}{2} + \frac{25}{4} - 30 + 2$

$= -\frac{37}{4}$

$\therefore f(5,-5/2) = -37/5$

d) at line segment OC, $y = 0$

$f(x,0) = x^2 + x\times0 + 0^2 - 6x + 2 = x^2 - 6x + 2$

$\therefore f_x = 2x - 6 = 0$

$\therefore x = \frac{6}{2} = 3$

$\therefore f(3,0) = 3^2 * 3\times0 + 0^2 - 6\times3 + 2 = 9 - 18 + 2 = -7$

$\therefore$ Hence absolute maximum is 11 at (0,-3), and absolute minimum is -10 at (4,-2).

* Find the linearization of :

a) $f(x,y) = x^2 - xy + \frac{1}{2}y^2 + 3$ at point (3,2).

→ Solution :-

given function $f(x,y) = x^2 - xy + \frac{1}{2}y^2 + 3$

and point $(x_1,y_1) = (3,2)$

Now,

$f_x = \delta(x^2 - xy + \frac{1}{2}y^2 + 3) = 2x - y$

at (3,2)

$f_x = 2\times3 - 2 = 6 - 2 = 4$

$f_y = \frac{\delta(x^2 - xy + \frac{1}{2}y^2 + 3)}{\delta y} = -x + \frac{1}{2}\times 2y$

$f_y = -x + y$ at (3,2)

$f_y = -3 + 2 = -1$

$f(3,2) = f(x_1,y_1)$

$= 9 - 1 = 8$

~~$= 3^2 - 3\times2 + \frac{1}{2}\times2^2 + 3$~~

~~$= 9 - 6 + \frac{4}{2} + 3$~~

~~$= \frac{18 - 12 + 4 + 6}{2}$~~

Method of Lagrange Multiplier :-

Suppose that $f(x,y,z)$ and $g(x,y,z)$ are differentiable and to find the local maximum and local minimum values of the function subject to constrains $g(x,y,z)=0$, we need to find the value of x, y, z and λ that simultaneously satisfy the equation,

$$\bar{\nabla} f = \lambda \bar{\nabla} g \text{ ---(i)}, \text{and}$$

$$g(x,y,z) = 0 \text{ --} ⑪$$

where,

λ = langrange Multiplier

$\bar{\nabla} f = f_x \vec{i} + f_y \vec{j} + f_z \vec{k}$

$\bar{\nabla} g = g_x \vec{i} + g_y \vec{j} + g_z \vec{k}$

* Find the greatest and smallest values that the function $f(x,y) = xy$ takes on the ellipse $\frac{x^2}{8} + \frac{y^2}{2} - 1 = 0$

→ Solution,

given function, $f(x,y) = xy$

subject to constrain $g(x,y) = \frac{x^2}{8} + \frac{y^2}{2} - 1 = 0$

Then, Vector gradient $\vec{\nabla} f$ of $f(x,y)$

$f_x = y \quad f_y = x$

$\therefore \bar{\nabla} f = y\vec{i} + x\vec{j}$

Then, Vector gradient $\bar{\nabla} f$ of $g(x,y)$

$$gx = \frac{\delta\left(\frac{x^2}{8}+\frac{y^2}{2}-1\right)}{\delta x}$$

$$= \frac{2x}{8} = \frac{x}{4}$$

$$gy = \frac{\delta\left(\frac{x^2}{8}+\frac{y^2}{2}-1\right)}{\delta y}$$

$$= \frac{2y}{2} = y$$

$$\therefore \bar{\nabla} g = gx\vec{i} + gy\vec{j}$$

$$\bar{\nabla} g = \frac{x}{4}\vec{i} + y\vec{j}$$

Now,

$$\bar{\nabla} f = \lambda \bar{\nabla} g$$

$$y\vec{i} + x\vec{j} = \lambda\left(\frac{x}{4}\vec{i} + y\vec{j}\right)$$

Equating both sides we get,

$$y = \frac{\lambda x}{4} \quad \text{and} \quad x = \lambda y$$

$$\therefore y = \frac{\lambda . \lambda y}{4}$$

or, $4y - \lambda^2 y = 0$

or, $y(4-\lambda^2) = 0$

$\therefore y = 0$

$\lambda = \pm 2$

then,

$g(x,y) = 0$

$\frac{x^2}{8} + \frac{y^2}{2} - 1 = 0$

when $y = 0$,

$\frac{x^2}{8} + \frac{0}{2} = 1$ $x^2 = 8$ $\therefore x = \pm\sqrt{8}$

$\therefore x = \pm 2\sqrt{2}$ why? $f(2\sqrt{2}, 0) = $ funct $(f(xy)) = 0$

$f(-2\sqrt{2}, 0) = f(xy) = 0$

$\therefore y = 0,\ x = \pm 2\sqrt{2}$, $\lambda = \pm 2$

$x = \lambda y$ W by equating $\lambda = \pm 2 \rightarrow$ by soln.

Put $x = \pm 2y$ in $g(x, y)$

Now

$\frac{x^2}{8} + \frac{y^2}{2} = 1$

or, $\frac{(\pm 2y)^2}{8} + \frac{y^2}{2} = 1$

or, $\frac{4y^2}{8_2} + \frac{y^2}{2} = 1$

or, $2y^2 = 2$

$\therefore y = \pm 1$, $x = \pm 2y$

In eqn $f(x,y) = xy$

when $y = +1$

$x = \pm 2 \times (+1) = \pm 2$

$\therefore (+2, +1)\ (-2, +1)$

$f(2, 1) = 2 \times 1 = 2$

$f(-2, 1) = -2 \times 1 = -2$

when $y = -1$

$x = \pm 2 \times (-1) = \pm 2$

$\therefore (2, 1)\ (-2, -1)$

$f(2, 1) = -1 \times 2 = -2$

$f(-2, -1) = -1 \times -2 = 2$

∴ The greatest value is 2 at (-2,-1) and (2,1) and the smallest value is -2 at (-2,1) and (2,2).

* Find the maximum and minimum Values of function $f_{xy} = 3x+4y$ on circle $x^2+y^2 = 1$.

→ Solution,

we have to find the value of x, y and λ which satisfy the condition,

$$\bar{\nabla} f = \lambda \bar{\nabla} g \text{ and } g(x,y)=0$$

Now,

$$f_x = 3 \quad , f_y = 4$$

$$\therefore \bar{\lambda} f = 3\vec{i} + 4\vec{j}$$

$$g_x = 2x \quad , g_y = 2y$$

$$\therefore \bar{\nabla} g = 2x\vec{i} + 2y\vec{j}$$

$$\therefore 3\vec{i} + 4\vec{j} = (2x\vec{i} + 2y\vec{j})\lambda$$

$$3\vec{i} + 4\vec{j} = 2x\lambda\,\vec{i} + 2y\lambda\,\vec{j}$$

Equating on both sides we get,

$$2x\lambda = 3 \quad , \quad 4 = 2y\lambda$$

$$\therefore x = \frac{3}{2\lambda} \quad \therefore y = \frac{4}{2\lambda}$$

Substituting thes values in $g(x,y)=0$, we get

$$x^2+y^2 = 1$$

$$\left(\frac{3}{2\lambda}\right)^2 + \left(\frac{4}{2\lambda}\right)^2 = 1$$

$$\text{or, } \frac{9}{4\lambda^2} + \frac{16}{4\lambda^2} = 1$$

$$\text{or, } 9+16 = 4\lambda^2$$

$25 = 4\lambda^2$

$\therefore \lambda^2 = \frac{25}{4}$

$\therefore \lambda = \sqrt{\frac{25}{4}} = \pm \frac{5}{2}$

Since $x = \frac{3}{2\lambda}$ and $y = \frac{4}{2\lambda}$, x and y have

~~sign~~ at $\lambda = 5/2$

For $x = \frac{3}{2\lambda}$ $\therefore x = \frac{3}{2 \times 5/2} = \frac{3}{5}$

at $\lambda = -5/2$

$x = \frac{3}{2 \times -5/2} = -\frac{3}{5}$

$\therefore x = \left(\frac{3}{5}, -\frac{3}{5}\right)$

For $y = \frac{4}{2\lambda}$, $y = \frac{4}{2 \times \frac{5}{2}} = \frac{4}{5}$ at $\lambda = 5/2$

at $\lambda = -5/2$

$y = \frac{4}{2 \times -5/2} = -4/5$

$\therefore y = \left(\frac{4}{5}, -\frac{4}{5}\right)$

x (1, 2)
y (4, 5)
then
Point are
(1,4) (1,5) (2,4) (2,5)
↓
as same
↓

then points are $\left(\frac{3}{5}, \frac{4}{5}\right), \left(\frac{3}{5}, -\frac{4}{5}\right), \left(-\frac{3}{5}, \frac{4}{5}\right)$

$\left(-\frac{3}{5}, -\frac{4}{5}\right)$

at fny $= 3x + 4y$

$\therefore f(3/5, 4/5) = 3 \times \frac{3}{5} + 4 \times \frac{4}{5} = \frac{9}{5} + \frac{16}{5} = \frac{25}{5} = 5$

$\therefore f(3/5, -4/5) = 3 \times \frac{3}{5} + 4 \times (-\frac{4}{5}) = \frac{9}{5} - \frac{16}{5} = -\frac{7}{5}$

$\therefore f(-\frac{3}{5}, \frac{4}{5}) = 3 \times (-\frac{3}{5}) + 4 \times \frac{4}{5} = -\frac{9}{5} + \frac{16}{5} = \frac{7}{5}$

$\therefore f(-\frac{3}{5}, -\frac{4}{5}) = 3 \times (-\frac{3}{5}) + 4 \times (-\frac{4}{5}) = -\frac{9}{5} - \frac{16}{5} = -\frac{25}{5} = -5$

$\therefore$ The maximum value of function is 5 at $f(3/5, 4/5)$

The minimum value of function is -5 at $f(-3/5, -4/5)$.

Then $u(x,t)$ is a function of v and w, $v = x + ct$

$\frac{\delta v}{\delta t} = c$ and $\frac{\delta v}{\delta x} = 1$

The solution can be obtained by introducing the two independent variable v and w defined by

$v = x + ct$ and $w = x - ct$

Differentiating v. w.r.t. x

$$\frac{\delta v}{\delta x} = \frac{\delta y}{\delta v} \cdot \frac{\delta v}{\delta x} + \frac{\delta y}{\delta w} \cdot \frac{dw}{\delta x}$$

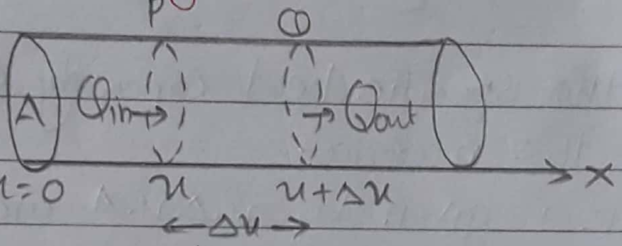
Mathematical Modeling of one dimensional Head flow



let us consider flow of head by conduction in an uniform bar with sides insulated so that the loss of heat from sides by conduction is neglegible.

Physical Assumption

i.) The bar is made up of heat conducting material.

ii.) The bar is uniform and thin so that the temp at all points of cross section is constant.

Let one end of the bar is placed at origin which is at higher temp. and u denotes temperature function. Then u at any point of the bar depends upon distance (x) and time (t). i.e. $u = u(x,t)$

The amount of heat flowing inside the section of bar depends on

a) Cross sectional area of bar. i.e. A

b) Thermal conductivity of bar i.e. k

c) Rate of temp w.r.t. to position i.e. $\frac{\delta u}{\delta x}$ (templ. gradient)

Let P and Q be two nearly points on bar at x and $x+\Delta x$ from origin.

The amount of heat flowing into Section PQ from P is given by

$$Q_{in} = -kA\left(\frac{\delta u}{\delta x}\right)_{x} \text{ --- } ①$$

the amount of heat flowing out from Q is given by

$$Q_{out} = -kA\left(\frac{\delta u}{\delta x}\right)_{x+\Delta x} \text{ --- (ii)}$$

[(-) indicate that x increases and u decreases]

from eqⁿ ① and eqⁿ (ii)

$$Q_{in} - Q_{out} = -kA\left(\frac{\delta u}{\delta x}\right)_{x} + kA\left(\frac{\delta u}{\delta x}\right)_{x+\Delta x}$$

heat gained in Section PQ is given by,

$$\therefore Q_{in} - Q_{out} = kA\left[\left(\frac{\delta u}{\delta x}\right)_{x+\Delta x} - \left(\frac{\delta u}{\delta x}\right)_{x}\right] \text{ --- (iii)}$$

Let s be the specific heat capacity and ρ be the density of the material.

The Volume is given by ~~x~~.Δx.A and mass = $\rho \cdot \Delta x \cdot A$

Then,

amount of heat gained by section PQ is,

= m×s× rate of change of temp per unit time

$$= \rho \cdot \Delta x \cdot A \times \frac{\delta u}{\delta t} \cdot s \text{ --- (iv)}$$

Since eqⁿ (iii) and (iv) are equal, so,

$$\frac{\delta u}{\delta t}\rho \Delta x s \cancel{A} = k\cancel{A}\left[\left(\frac{\delta u}{\delta x}\right)_{x+\Delta x} - \left(\frac{\delta u}{\delta x}\right)_{x}\right]$$

$$\therefore \frac{\delta u}{\delta t} = \frac{k}{\rho s}\,\frac{\left[\left(\frac{\delta u}{\delta x}\right)_{x+\Delta x} - \left(\frac{\delta u}{\delta x}\right)_{x}\right]}{\Delta x}$$

taking limit $\Delta x \to 0$ on both sides.

$$\lim_{\Delta x \to 0}\frac{\delta u}{\delta t} = \lim_{\Delta x \to 0}\frac{k}{\rho s}\,\frac{\left[\left(\frac{\delta u}{\delta x}\right)_{x+\Delta x} - \left(\frac{\delta u}{\delta x}\right)_{x}\right]}{\Delta x}$$

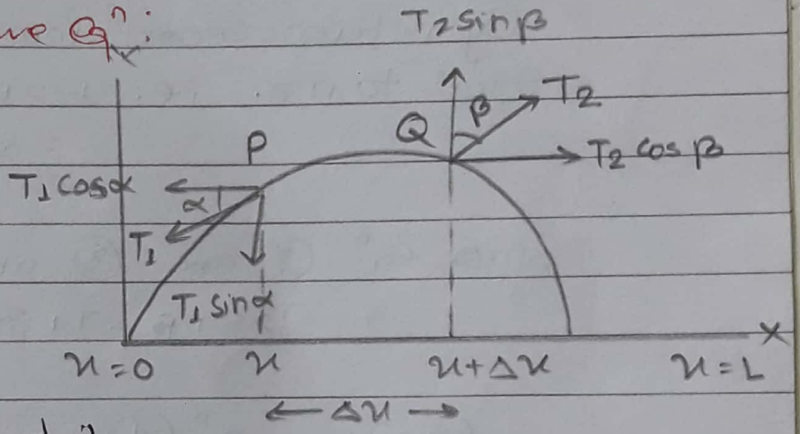
or, $\frac{\delta u}{\delta t} = \frac{k}{s s} \cdot \frac{\delta^2 u}{\delta x^2}$

or, $\boxed{\frac{\delta u}{\delta t} = c^2 \frac{\delta^2 u}{\delta x^2}}$ where $c^2 = \frac{k}{s s}$ is diffusivity of material.

$\boxed{\therefore u_t = c^2 u_{xx}}$ is required P.D.E of One dimensional heat flow eq^n.

Mathematical modeling of wave eq^n:

Physical assumption:



i> The motion takes place on the vertical plane only and each particle of string execute transvers vibration only.

ii> The string is perfectly elastic and it transmit tension only but not bending and sharing force.

iii> The motion of string is Subject to only a Constant tension (T) and no other external forces.

Consider an elastic string of length 'L' (when it is stretched). Fix two ends of String at $x = 0$ and $x = L$ along x-axis.

let $u(x,t)$ denotes deflection of string at any position 'x' & time 't'. Consider a portion PQ of the string. Since there is no resistance to bending the tension is traditional to the string at each point.

Let T_1 and T_2 be the tension at P and Q respectively.

Since the points of string moved vertically, there is no motion in the horizontal direction, so that the tension produced at horizontal Component must be Constant. i.e.

$$T_1 \cos \alpha = T_2 \cos \beta = T = \text{Constant} \longrightarrow ①$$

The vertical Component T1 and T2 are $-T_1 \sin\alpha$ and $T_2 \sin\beta$ at P and Q respectively.

Resultant force acting on the portion PQ of the string is given by

$$T_2 \sin\beta - T_1 \sin\alpha \quad --- ②$$

Let ρ be the mass of undeflected string per unit length.

i.e. $\rho = \frac{m}{\Delta x}$, $m = \rho . \Delta x$

By newton second law of motion, The resultant force is equal to ma. i.e. $F = ma$, $a = \frac{\delta^2 y}{\delta t^2}$

$$= \rho . \Delta x . \frac{\delta^2 y}{\delta t^2} \quad --- ③$$

Since eqn ② and ③ are equal so,

$$T_2 \sin\beta - T_1 \sin\alpha = \rho . \Delta x . \frac{\delta^2 y}{\delta t^2} \quad - ④$$

Dividing eqn ④ by eqn !

$$\frac{\cancel{T_2} \sin\beta}{\cancel{T_2} \cos\beta} - \frac{T_1 \sin\alpha}{\cancel{T_1} \cos\alpha} = \frac{\rho \Delta x}{T} . \frac{\delta^2 y}{\delta t^2}$$

$$\therefore \frac{\delta^2 y}{\delta t^2} = \frac{T}{\rho \Delta x} (\tan\beta - \tan\alpha)$$

Since $\tan\beta$ and $\tan\alpha$ are slopes of string at $x + \Delta x$ and x.

$$\tan\alpha = \left(\frac{\delta y}{\delta x}\right)_x . \qquad \tan\beta = \left(\frac{\delta y}{\delta x}\right)_{x+\Delta x}$$

then eqn ④ becomes,

$$\frac{\delta^2 y}{\delta t^2} = \frac{T}{\rho \Delta x}\left(\left(\frac{\delta y}{\delta x}\right)_{x+\Delta x} - \left(\frac{\delta y}{\delta x}\right)_x\right)$$

taking limit $\Delta x \to 0$ on both sides,

$$\lim_{\Delta x \to 0} \frac{\delta^2 y}{\delta t^2} = \lim_{\Delta x \to 0} \frac{T}{\rho} \frac{\left(\frac{\delta y}{\delta x}\right)_{x+\Delta x} - \left(\frac{\delta y}{\delta x}\right)_x}{\Delta x}$$

So, $\frac{\delta^2 y}{\delta t^2} = \frac{T}{s} \frac{\delta^2 y}{\delta x^2}$ $\boxed{c^2 = \frac{T}{s}}$

$\boxed{\therefore u_{tt} = c^2 u_{xx}}$ is the p.d.e of wave eqn
